## 1 ABSTRACT

A decomposition technique has been developed which greatly reduces the time and computer memory space required to implement the Han-Powell Optimization Algorithm. The technique requires the solution of a Quadratic Programming Problem (QPP) in the space of the decision variables only, rather than in the space of the entire set of variables as in the original algorithm published by Powell.

## 2 INTRODUCTION

Early attempts at optimal flowsheet simulation utilized a flowsheeting system in an "inner loop" to converge the equality constraints defining a flowsheet while an optimizer in the "outer loop" chose values of the parameters over which the flowsheet was optimized (see for example Friedman and Pinder, 1972). The optimizer generally used a pattern search method such as the Complex Method (Box, 1965) to choose values of the decision variables. Such methods are usually dependable, but require much computation and have trouble handling inequality constraints.

Recently, techniques have been developed which converge the equality constraints defining a flowsheet while moving towards the optimal values of the decision variables. The equality constraints may only be satisfied at the last iteration, at which time the decision variables reach their optimal values. One such technique is that developed by Powell (1977) based on work done by Han (1975). A quadratic program with linearized versions of the flowsheet equality and inequality constraints is set up and solved at each iteration. The quasi-Newton approximation to the Hessian Matrix for the QPP is the size of the number of variables in the problem, and is not generally sparse. A problem with 1000 variables would require 1,000,000 storage locations for the approximate Hessian Matrix.

Bema, Locke, and Westerberg (1980) developed an efficient implementation of Powell's algorithm to be used with a simulation program based on equation solving methods. That algorithm decomposes the computations for the problem so that the required Hessian is never handled directly. Biegler and Hughes (1981, 1982) have implemented the Han-Powell algorithm with a sequential modular simulation package. In their work the QPP is set up in the space of the decision variables and the torn variables of the recycle streams. Murtagh (1982) has developed a Lagrangian based optimization procedure (Robinson, 1974) which also simultaneously solves and optimizes flowsheet equations. The method uses the MINOS/AUGMENTED nonlinear

programming system (Murtagh and Saunders, 1980) to solve and optimize the flowsheet equations. The technique seems quite promising when the flowsheet equations are mostly linear.

The technique presented here is a variation of Powell's algorithm (1977). As mentioned previously, this algorithm sets up a QPP in the space of the decision variables. It is computationally more efficient and conceptually cleaner than the algorithm described in Berna, Locke, and Westerberg (1980). The algorithm is very similar to an incorrect algorithm reported by Berna and two of the present authors several years ago (Berna, Locke, and Westerberg, 1978). Unfortunately that algorithm included an incorrect step, and it failed when tested on large problems. Work done by Edahl (1982) on the Han-Powell algorithm includes this algorithm as a subset of a broader class being investigated.

### 3 THEORY

The optimization problem can be stated as follows:

$$\begin{aligned} & \min \Phi(z) \\ & \text{s.t. } g(z) = 0 \\ & z_{\min} \leq z \leq z_{\max} \\ & z \in E^{n+r} \\ & g: E^{n+r} \rightarrow E^n \\ & \kappa: E^{n+r} \rightarrow E^1 \end{aligned} \quad (P1)$$

The Lagrangian of this problem is:

$$L(z, r, \kappa_{\min}, \kappa_{\max}) = \Phi(z) - r^T g(z) - \kappa_{\min}^T (z_{\min} - z) + \kappa_{\max}^T (z_{\max} - z),$$

with  $r$  the Lagrange multipliers on the equality constraints and  $\kappa_{\min}$  and  $\kappa_{\max}$  the Kuhn-Tucker multipliers on the lower and upper bounds of  $z$ , respectively.

The Kuhn-Tucker conditions for this problem are:

$$\kappa_{\min}^T (z_{\min} - z) = 0$$

$$* \begin{matrix} [z & - z] = 0 \\ \max & \max \\ \llcorner_{\min} & \llcorner_{\max} \end{matrix} \quad \text{£ } 0$$

For a typical flowsheet calculation of the type we are considering,  $n$  may be on the order of 10,000, with  $r$  on the order of 10. This formulation is quite general as general inequality constraints can be converted to equality constraints through the use of bounded slack variables.

Powell's approach to solving this problem is to linearize the equality constraints, assume a quadratic approximation to the objective function, and solve the resulting QPP. Variables are then updated by taking the step

$$Az = ad$$

where  $d$  is the step calculated by the QPP.

As stated previously, the disadvantage of using Powell's method is the size of the Hessian Matrix for the QPP. For a problem with 10,000 variables, the Hessian contains 100 million elements, far too many for even the most advanced machines to handle. By partitioning the variables into two sets, the independent or decision variables,  $u$ , and the dependent or pivoted variables,  $x$ , we now show how a QPP can be set up in the decision variables only.

Let  $x_k$  and  $u_k$  be the values of the dependent and independent variables respectively at the present iteration. Linearizing the equality constraints about this point gives:

$$g(x_{k+1}, u_{k+1}) \sim g(x_k, u_k) + \text{Og}/3x^T)_k Ax_R + \text{Og}/3u^T)_k Au_k$$

Setting  $g(x_{k+1}, u_{k+1})$  equal to 0, and requiring that  $\text{Og}/3x^T)_k$  be nonsingular yields:

$$Ax_R = - \text{Og}/3x^T)_k^{-1} \{g(x_k, u_k) + \text{Og}/3u^T)_k Au_k\}$$

For any choice of  $Au_k$ , a value for  $Ax_R$  can be calculated. The problem can then be stated as one to calculate  $Au_k^*$ , the optimal change in the decision variables:

$$\min F(Au_k)$$

$$Au_k$$

$$\text{s.t. } u_{\min} - u_k \leq \Delta u_k \leq u_{\max} - u_k$$

$$x_{\min} - x_k \leq -(\partial g/\partial x^T)_k^{-1} \{g(u_k, x_k) + (\partial g/\partial u^T)_k \Delta u_k\} \leq x_{\max} - x_k \quad (P2)$$

$$\Delta u_k \in E^r$$

$$x_k \in E^n$$

$$g: E^{n+r} \rightarrow E^n$$

where

$$F(\Delta u_k) = \Phi(x_k + \Delta x_k, u_k + \Delta u_k).$$

Expanding  $F(\Delta u_k)$  in a Taylor series about the point  $\Delta u_k = 0$  yields the following QPP associated with (P2):

$$\begin{aligned} \min_{\Delta u_k} \left\{ Q(\Delta u_k) \mid Q(\Delta u_k) = a_k + b_k^T \Delta u_k + \frac{1}{2} \Delta u_k^T C_k \Delta u_k \right\} \\ \text{s.t.} \quad u_{\min} - u_k \leq \Delta u_k \leq u_{\max} - u_k \\ -(\partial g/\partial x^T)_k^{-1} (\partial g/\partial u^T)_k \Delta u_k \leq x_{\max} - x_k + (\partial g/\partial x^T)_k^{-1} g(x_k, u_k) \\ (\partial g/\partial x^T)_k^{-1} (\partial g/\partial u^T)_k \Delta u_k \leq x_k - x_{\min} - (\partial g/\partial x^T)_k^{-1} g(x_k, u_k) \end{aligned} \quad (P3)$$

$$\Delta u_k \in E^r$$

$$x_k \in E^n$$

$$g: E^{n+r} \rightarrow E^n$$

The vector  $b$  is the reduced gradient  $\delta\Phi/\delta u$ , calculated by doing a Taylor series expansion on the objective function:

$$\Phi(x+\Delta x, u+\Delta u) = \Phi(x, u) + (\partial\Phi/\partial x^T)\Delta x + (\partial\Phi/\partial u^T)\Delta u$$

but

$$Ax = -0g/3x^T r^1 \{g(x,u) \cdot @g/3u^T Au\}$$

then

$$\begin{aligned} A^* &= -O^*/8x^T \{(3g/8x^T)^{-1} \{g(x,u) \cdot Og/3u^T Au\}\} \cdot \langle 4 \rangle / 3u^T Au \\ &= -\rangle^*/8x^T X \odot g/ax^T r^1 g \langle x.u \rangle \cdot \{(34 \rangle / 8u^T) - (34 \rangle / 3x^T X (3g/3x^T r^1 (3g/3u^T))\} Au \end{aligned}$$

The coefficient of Au gives the constrained derivative of • with respect to u:

$$b_k = 6^*1 Su = O^*/du) - \{og/SxV'Og/Su^1)\}^7 \odot * \wedge.$$

The fact that  $g(x,u)$  is not 0 does not effect the term  $b_R$ . It simply adds something to the scalar  $a_k$ .

The matrix C is an approximation to the Hessian of the Lagrange Function formed from the problem:

$$\min \{u, x(u)\}$$

$$\text{s.t. } u \cdot \begin{matrix} \text{mm} & \text{max} \end{matrix} \quad \begin{matrix} \text{mm} & \text{max} \end{matrix} u$$

$$x_{\min} * x(u) * x_{\max}$$

(P4)

$$x(u): g(x,u) = 0$$

$$u \in E^r$$

$$x \in E^n$$

The Lagrange of (P4) is:

$$\begin{aligned} L &= \{u, x(u)\} - B^T \cdot [u \cdot \begin{matrix} \text{mm} & \text{max} \end{matrix} u] + J3^T [u \cdot \begin{matrix} \text{mm} & \text{max} \end{matrix} u] \\ &- \#^T_{\min} [x_{\min} - x(u)] + \#^T_{\max} [x_{\max} - x(u)]. \end{aligned}$$

C is initialized to the identity matrix and updated each iteration using the Broyden-Fletcher-Goldfarb-Shanno (BFGS) updating formula, as suggested by Powell.

We also follow Powell's suggestion in calculating the step-size parameter,  $a$ :

Define  $V(a)$  as:

$$\begin{aligned} \Psi(a) &= \Phi(u^*, x^*) + \sum \mu_i |g_i(u^*, x^*)| \\ &+ \sum \zeta_{i,\max} |u_{i,\max} - u_i| \cdot H c^J u_i - u_{i,\max} J \\ &+ \sum v_{i,\max} |x_{i,\max} - x_i| + \sum v_{i,\min} |x_i - x_{i,\min}| \end{aligned}$$

where

$$u^* = u_k + a d_k$$

$$x^* = x - a (\partial g / \partial x^T)^{-1} \{g(u_k, x_k) + (\partial g / \partial u^T)_k d_k\}$$

and  $\mu_i$ ,  $\zeta_{i,\max}$ ,  $\zeta_{i,\min}$ ,  $v_{i,\max}$  and  $v_{i,\min}$  are defined as

$$1/\mu_i = \max\{|X_i|, V_i (1/\mu_i^* + |X_i|)\}$$

$$\zeta_{i,\max} = \max\{U_{i,\max} |c_{j,\max}^* \cdot u_{j,\max}| \}$$

$$\zeta_{i,\min} = \max\{|v_{i,\min}^*|, V_i (1/\mu_i^* + |A_{i,\min}|)\}$$

$$v_{i,\max} = \max\{|r_{i,\max}|, V_i (v_{i,\max}^* + |a_{i,\max}|)\}$$

$$v_{i,\min} = \max\{|U_{i,\min}|, V_i (v_{i,\min}^* + |a_{i,\min}|)\}$$

Note that values with a  $*$  indicate the value of that parameter at the previous iteration.  $X_i$  is the current value of the Lagrangian multiplier for the equality constraints of the original problem, (P1).  $X$  is calculated by:

$$\lambda = (\partial g / \partial x^T)^{-1} \{x_{\max} - x_{\min} - (\partial \Phi / \partial x)\}.$$

$it_{\max}$  and  $it_{\min}$  are the Kuhn-Tucker multipliers associated with the inequality constraints derived from upper and lower bounds on the pivoted variables  $x$  and are calculated by the QPP associated with problem (P2).  $\lambda_{\max}$  and  $\lambda_{\min}$  are Kuhn-Tucker

multipliers associated with the upper and lower bounds of the decision variables, and are also calculated by the QPP. At each iteration the value of  $a$  used is the first one found which satisfies  $VfclOf(0)$ . Usually  $a$  is 1, except perhaps for the first iterations.

#### 4 THE ALGORITHM

Step 0: Initialization

- i) Set  $k=0$ ,  $\theta=1$ ,  $i_0=0$  (with  $C^I$ , the first direction predicted is the steepest descent direction).
- ii) Initialize all variables  $z^C x^u$

Step 1: Compute the Jacobian and Reduced Gradient

- i) Increment  $k$
- ii) Evaluate  $(d^*/dz)$ ,  $g(z)$  and  $Og/3z^T$  at  $z_R$
- iii) Perform forward Gaussian elimination to partition the Jacobian and find the L/U factors for  $(8g/dx^T)_k$
- iv) Perform backward substitution to solve
 
$$Og/8x^T [v_k, A_k] = [g, Og/3u^T]_k$$
 for  $[v_k, A_k]$ 
 and solve  $Og^T/3x)X^*_k = O^*/8x)_k$  for  $X^*_k$
- v) Compute the reduced gradient
 
$$(\delta\Phi/\delta u)_k = (\partial\Phi/\partial u)_k - A_k^T (\partial\Phi/\partial x)_k$$
- vi) If  $k < 2$ , go to Step 3; otherwise go to Step 2.

Step 2: Update  $C$  (a la Powell's suggestions)

- i)  $\gamma_k = (\delta\Phi/\delta u)_k - A_k [\sigma_{\min} - \sigma_{\max}]_{k-1} - \omega_{k-1}$
- ii) let  $\delta_k = \theta \gamma_k + (1-\theta)C_{k-1} \delta_{k-1}$

where

$$\delta = 1 \text{ if } \langle \mathbf{a}_{k-1}^T \mathbf{y}_k \rangle \leq -2 \mathbf{a}_{k-1}^T \mathbf{C}_{k-1} \mathbf{a}_{k-1}$$

and otherwise

set

$$\rho = \frac{\mathbf{c}_{k-1}^T \mathbf{f} \mathbf{C}_{k-1} \mathbf{c}_{k-1}}{[\delta_k \mathbf{V}_k \mathbf{C}_{k-1} \delta_{k-1} - \delta_{k-1}^T \mathbf{y}_k]}$$

$$\text{iii) Set } \mathbf{C}_k = \mathbf{V}_k - [\mathbf{C}_{k-1} \delta_{k-1} \delta_{k-1}^T \mathbf{C}_{k-1}] / [\delta_{k-1}^T \mathbf{C}_{k-1} \delta_{k-1}] \\ + \frac{\mathbf{a}_{k-1} \mathbf{a}_{k-1}^T}{[\delta_{k-1}^T \mathbf{y}_k]}$$

Step 3: Solve Associated QPP

$$\text{i) Define } Q(\mathbf{A}\mathbf{u}_k) = Q(\mathbf{x}, \mathbf{u}) + (\mathbf{a}^* / \langle \mathbf{u}^T \rangle) \mathbf{A}\mathbf{u}_k + \frac{1}{2} \mathbf{A}\mathbf{u}_k^T \mathbf{C}_k \mathbf{A}\mathbf{u}_k$$

ii) Let  $\mathbf{d}_k$  be the solution to the following QPP:

$$\min_{\mathbf{A}\mathbf{u}_k} Q(\mathbf{A}\mathbf{u}_k)$$

$$\text{s. t. } - \mathbf{A}_k \mathbf{A}\mathbf{u}_k \leq \mathbf{X}_{MX} - \mathbf{x}_k + \mathbf{v}_k$$

$$\mathbf{A}_k^T \mathbf{A}\mathbf{u}_k \leq \mathbf{S}_k - \mathbf{x}_{\min} + \mathbf{v}_k$$

$$\mathbf{U}_A - \mathbf{U}_k \leq \mathbf{A}\mathbf{u}_k \leq \mathbf{U}_k - \mathbf{U}_k$$

Step 4: Compute Step Size Parameter,  $a_k$

$$\text{i) Calculate } \mathbf{X}_{k-1} = \mathbf{O} \mathbf{g}^T / 3 \mathbf{X} \text{ "1} [ * \mathbf{v}_{\max} - \mathbf{v}_{\min} ] - \mathbf{X}^*$$

$$\text{ii) Set } \mathbf{p}_k = \mathbf{A}_k \mathbf{d}_k + \mathbf{v}_k$$

$$\text{iii) Set } \beta_{ik} = \max\{ |\mathbf{X}_{ik}|, h_{i, |k-1|} * \|\mathbf{J}\| \}$$

$$\zeta_{ik, \max} = \max\{ |\beta_{ik, \max}|, \frac{1}{2} (\zeta_{i(k-1), \max} + |\beta_{ik, \max}|) \}$$

$$\zeta_{ik, \min} = \max\{ |\beta_{ik, \min}|, \frac{1}{2} (\zeta_{i(k-1), \min} + |\beta_{ik, \min}|) \}$$

$$\sigma_{ik, \max} = \max\{ |\mathbf{x}_{ik, \max} - \mathbf{x}_k|, \frac{1}{2} (\sigma_{i(k-1), \max} + |\mathbf{x}_{ik, \max}|) \}$$

$$\sigma_{ik, \min} = \max\{ |\mathbf{x}_{ik, \min}|, \frac{1}{2} (\sigma_{i(k-1), \min} + |\mathbf{x}_{ik, \min}|) \}$$

$$\text{iv) Select } \langle \mathbf{G}[\mathbf{O}, \mathbf{I}] \rangle_k \text{ such that } \Psi(\mathbf{x}^*, \mathbf{u}^*, //k) < \Psi(\mathbf{x}_k, \mathbf{u}_k, \mu_k)$$

$$\text{where } \Psi(\mathbf{x}, \mathbf{u}, i) = 4 \langle \mathbf{x}, \mathbf{u} \rangle + //^T |\mathbf{g}(\mathbf{x}, \mathbf{u})|$$

$$+ C_{\max}^T |u - u_1| + C_{\min}^T |u - u_4|$$

$$+ v_{\max}^T |x - x_1| + v_{\min}^T |x - x_m|$$

$$x^* = \dots$$

$$\ll \dots u_k + \alpha d_k$$

v) Set  $ix_k = x^*$ ;  $u_k = u^*$ ;  $\delta_k = \alpha_k d_k$

vi) Let  $io_k = (\partial\Phi/\partial u)_k - A_k [x_{\min} - x_{\max}]_k$

Step 5: Check for Convergence

If  $(d_k^T \delta_k + \rho_k^T \delta_k) < \epsilon$  then go to step 6;

otherwise go to Step 1

Step 6: Stop

The only differences between this algorithm and the one published by Berna et al. (1978) occur in Step 2 part i (calculation of  $y_k$ ) and in Step 4 part i (calculation of  $V$ ).

## 5 DISCUSSION

It is of interest to compare this algorithm with both the Berna et al. 1980 algorithm and the one used in MINOS/AUGMENTED. We can do this by examining the final  $C^*$  matrix that is approximated by the three algorithms, where  $C^*$  is the Hessian matrix projected into the subspace of the decision variables  $u$ . The  $C^*$  matrix for all three algorithms is given by:

$$C^* = \begin{bmatrix} I & -A^T \\ \begin{bmatrix} f_{02} \\ U d^2 U dx du^T \end{bmatrix} & \begin{bmatrix} @^2 L / 8 u^8 x^T \\ (d^2 U dx dx^T) \end{bmatrix} \end{bmatrix} \begin{bmatrix} I \\ -A \end{bmatrix}$$

where matrix  $A$  is calculated from

$$A = \{dg/dx^j\} - H dg/du^T$$

and

$$L(x,u,X) = 4Kx,u) - X^T g(x,u)$$

and all functions are evaluated at the solution,  $(x^*, u^*, X^*)$ . For clarification we are ignoring the terms added to the Lagrange function by upper and lower bounds. These terms drop out when second derivatives are taken.

In the Berna et al. 1980 version, the current point  $(x_p, u_p, X_p)$  and the previous point  $(X_Q, U_Q)$  are used to update the matrix  $H_Q$  in such a way that  $H_1$  satisfies the secant relationship, where  $H$  is an approximation to the Hessian matrix:

$$H_1 \begin{bmatrix} u_1 - u_0 \\ x_1 - x_0 \end{bmatrix} = \begin{bmatrix} \partial/\partial u [L(x_1, u_1, \lambda_1) - U_{X_0, u_0, \lambda_1}] \\ d/dx C U_{X_1, u_1, X_1} - L U_{X_0, u_0, \lambda_1} \end{bmatrix}$$

One of the variable metric method (VMM) update formulae is used to calculate matrix  $H_1$ . The desired  $H^*$  is then

$$H^* = \begin{bmatrix} (\partial^2 L / \partial u \partial u^T) & 0^2 L / 3 u d x^T \\ (\partial^2 L / \partial x \partial u^T) & 0^2 U 3 x 8 x^T \end{bmatrix}$$

evaluated at  $(x^*, u^*, X^*)$ .

$C_1$  is constructed by computing

$$C_1 = [I \quad -A^T] H_1 \begin{bmatrix} I \\ -A \end{bmatrix}$$

In MINOS/AUGMENTED, the current point  $(x_r, u^r, X^r)$  is used to generate a new function,  $f\{u\} (x^r, u^r, X^r)$ :

$$f\{u\} (x_r, u_r, X_r) = \phi\{(x_1 - (A \cdot (u - u_1)), u) - X^T_1 g\{(x_1 - (A \cdot (u - u_1)), u)\}$$

where  $(A)_1$  indicates matrix  $A$  evaluated at the point  $(x_r, u^r)$ .

By using gradients of  $f$  at various values of  $u$ , the Hessian of  $f$  is approximated by VMM updating formulae. The Hessian of  $f$  at  $x_1$  is given by:

$$\begin{aligned} \partial/\partial u f\{u\} (x_r, u_r, X^r) &= \partial/\partial u \{4Kx_r, u_1) - X^T_1 g(x_1, u_1)\} + \partial/\partial x \{ \phi(x_1, u_1) \\ &+ X^T_1 g(x_1, u_1) \} (A)_1 \end{aligned}$$

$$\frac{\partial^2 f(u)}{\partial u \partial u^T} \Big|_{(x_1, u, X)} = [I, -(A)] \begin{bmatrix} \frac{\partial^2 L_1}{\partial u \partial u^T} & \frac{\partial^2 L_1}{\partial u \partial x^T} \\ \frac{\partial^2 L_1}{\partial x \partial u^T} & \frac{\partial^2 L_1}{\partial x \partial x^T} \end{bmatrix} \begin{bmatrix} I \\ -(A)_1 \end{bmatrix}$$

where  $L_1$  is  $L$  evaluated at the point  $(x_1, u, X)$ .

It is easily seen that for both of these algorithms the matrix  $A$  plays an important part in the approximation of  $C^*$ . Under the assumption that  $f(u | x_1, u, X)$  and  $L(x, u, X)$  are quadratic functions (actually that the quadratic approximation is locally sufficient), then the  $C$  matrix is a quadratic approximation to  $L(x^*, u^*, X^*)$  projected onto the subspace where  $x - x_1 = -(A^* u - u_0)$ .

Now consider the algorithm given here. Examine the parametric programming problem:

$$P(u): \min_x \Phi(x, u)$$

$$g(x, u) = 0$$

Since it is assumed that  $g(x, u)$  has a unique solution  $x(u)$  for each  $u$ ,  $P(u)$  has a unique optimal solution. Define  $\Phi^*(u)$  as the value of  $P(u)$ . It is known that:

$$1. \Phi^*(u) = \Phi(x(u), u) = X^T(u) \nabla_x g(x(u), u)$$

$$2. \frac{\partial^2 \Phi^*(u)}{\partial u \partial u^T} = [I, -(A)^T] \begin{bmatrix} \frac{\partial^2 L}{\partial u \partial u^T} & \frac{\partial^2 L}{\partial u \partial x^T} \\ \frac{\partial^2 L}{\partial x \partial u^T} & \frac{\partial^2 L}{\partial x \partial x^T} \end{bmatrix} \begin{bmatrix} I \\ -A \end{bmatrix}$$

where  $x = x(u)$

$$X(u) = -\frac{\partial g(x(u), u)}{\partial x} \Big|_{x=x(u)}$$

$L$  evaluated at the point  $(u, x(u), X(u))$ .

Note that  $C^* = \frac{\partial^2 \Phi^*(u^*)}{\partial u \partial u^T}$ . If it is assumed that  $\Phi^*(u)$  is quadratic, then a VMM

update formula using  $\partial\Phi^*(u)/\partial u$  at various values of  $u$  should construct an approximation to  $C^*$ . The algorithm presented here proceeds in this manner (except of course that  $x(u)$  may not be computed exactly). It attempts to construct  $C^*$  directly -- not as a quadratic approximation to the Lagrangian projected onto a subspace. Hence the curvature of  $x(u)$  is taken into account.

## 6 SAMPLE PROBLEMS

In this section we present the results of two test problems solved using the algorithm described in the previous section. The algorithm has been imbedded into the ASCEND-II flowsheet system (Locke, 1981). Modules describing these test problems were written and added to the system.

### 6.1 DETAILED SOLUTION OF A SMALL PROBLEM

We wish to solve the problem:

$$\begin{aligned} & \min\{\Phi\} \\ \text{s.t.} \quad & ab + bc - 1 = 0 = g_1 \\ & \Phi - a^2 - b^2 + c = 0 = g_2 \\ & 0 \leq a, b, c \leq 1 \end{aligned}$$

Throughout the calculations variables  $\Phi$  and  $a$  were the pivoted variables, while  $b$  and  $c$  were the independent (decision) variables. Initial values were:  $a=0$ ,  $b=1$ ,  $c=1$ ,  $\Phi=0$ . Also, at the start we set  $\mu_0=0$ , and  $C_1=1$ .

The starting point gives an initial Jacobian Matrix of:

$$\begin{array}{ccccc} & a & b & c & \Phi \\ \begin{array}{c} g_1 \\ g_2 \end{array} & \begin{bmatrix} 1 & & & & \\ 0 & & & & \end{bmatrix} & \begin{array}{c} 1 \\ -2 \end{array} & \begin{array}{c} 1 \\ 1 \end{array} & \begin{bmatrix} 0 \\ 1 \end{bmatrix} \end{array}$$

With  $\Phi$  and  $a$  as pivoted variables, the matrix  $(\partial g/\partial x^T)$  is the identity matrix.

The initial right-hand-side vector ( $g$ ) is  $[0,0]$ , so the vector  $v$  is also  $[0,0]$ , while the matrix  $A$  is calculated to be:

$$\begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix}$$

The initial QPP is:

$$\min_{[ACJ]} [2 \ -1] \cdot V_z [Ab \ Ac] \begin{bmatrix} i \\ j \\ k \end{bmatrix}$$

$$\text{s.t. } \begin{matrix} -1 \leq Ab \leq 0 \\ -1 \leq Ac \leq 0 \end{matrix}$$

$$\begin{bmatrix} -1 \\ -\infty \end{bmatrix} \leq \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} \Delta b \\ \Delta c \end{bmatrix} \leq \begin{bmatrix} 0 \\ \infty \end{bmatrix}$$

The solution to this QPP is  $[-1, 0]$ . The Lagrange multipliers on the original equality constraints are  $[0, -1]$ . Table 1 summarizes the search for  $a$  such that  $YU) < Y(0)$ .

Table 1: Search for  $a$

$a$	$\Phi$	$Za$	$\Psi$
0.0	0.0	0.0	0.0
0.25	-0.375	0.125	-0.25
0.5	-0.5	0.5	0.0
0.75	-0.375	1.125	0.75
1.0	0.0	2.0	2.0

Using a step size of .25, the variable values after the first iteration are:  $a=.25$ ,  $b=.75$ ,  $c=1$ ,  $d=-.5$

Throughout the remaining iterations,  $c=1$  and  $d=-1$ . The constrained derivative for iteration 2 is:  $\nabla f = [-0.6667, -1.5]$  and the Hessian Matrix after the first update is:

$$\begin{bmatrix} 5.33 & 2 \\ 2 & 1.891 \end{bmatrix}$$

Table 2 shows the progress of the calculations to the solution.

**Table 2:** Progress of the Calculations

<u>Iteration</u>	<u>a</u>	<u>b</u>	<u>RHS</u>	<u><math>\theta</math></u>
0	0.0	1.0	0.0	0.0
1	0.25	0.75	0.0988	-0.5
2	0.5417	0.6250	0.0757	-0.4170
3	0.3910	0.7101	0.0232	-0.3738
4	0.3947	0.7170	5.4E-5	-0.3301
5	0.3308	0.7498	3.9E-3	-0.3345
6	0.3780	0.7248	2.2E-3	-0.3346
7	0.3815	0.7238	9.6E-6	-0.330514
8	0.3807	0.7242	5.7E-7	-0.330501
9	0.3803	0.7245	2.1E-7	-0.330501
10	0.380278	0.724492	7.6E-13	-0.330500

## 6.2 OTHER COMPUTATIONAL EXPERIENCE

The algorithm has been applied to several flowsheeting problems. The largest contained 156 generally non-linear equations with 161 calculated variables, leaving 5 degrees of freedom. The algorithm was able to find the optimal solution to this problem without difficulty. Typical convergence was in 10 to 20 iterations for all problems.

## 7 ACKNOWLEDGMENT

This work was partially funded by NSF Grant ECS-8026777 (Edahl) and by a grant from the Exxon Corporation (Locke and Westerberg).
