CHAPTER 2*

Institutional, Funder, and Journal Data Policies

Kristin Briney, Abigail Goben, and Lisa Zilinski

Data curation exists within a larger framework of laws and policies covering topics like copyright and data retention. These obligations must be considered in order to properly care for data as it is being created and preserved. While laws may transition slowly, the policies applying to research data by funding bodies, institutions, and journals have seen significant change since the turn of the century. These policies have directly impacted the practices of researchers and prompted the creation of data curation services by many libraries in partnership with their larger institutions.

This chapter examines three important categories of policies, primarily covered from the US perspective, that affect data curation practices in libraries: funding agency policies, institutional data policies, and journal data policies. While data professionals may be more familiar with funder and journal policies, institutional data policies are emerging as equally prevalent. Also, researchers across disciplines may encounter policies at a more granular level, such as for a specific research project or group, but these policies are less standardized and are therefore not covered in detail here.

Data policies are presently developing as researchers, institutions, funders, and journals look to improve research data management and sharing practices. As a result, standards for data policies have not yet been fully established. Potential topics covered in data policies include statements of data ownership, sharing

requirements, expected retention periods, access rights, and security issues. These may appear in a stand-alone policy or in multiple policy documents depending on the policy creator. While some homogenization may develop over time, the high levels of variance between policies from different sources—funders, institutions, and journals—and even between policies from similar sources, prevent the identification of consistent policy standards that cross all disciplinary and local boundaries.

Instead, this chapter outlines the similarities and differences between the general trends in funder, institutional, and journal policies, which are critical to understand. In particular, we must understand how the inconsistencies between these three policy types can cause challenges for researchers trying to meet overlapping requirements. This chapter will briefly recap the current state of these policy three areas, identify common overlap and variances, and suggest how we, as we undertake data curation, can navigate and influence this policy landscape.

**Funding Agency Data Policies**

Funding agency policies have served a critical role in driving efforts on data curation as these policies primarily require researchers to preserve and share their data. While the policies themselves are mainly researcher-focused, libraries have an important role to play in this area due to their preservation expertise.

One of the first data policies by a major funding agency in the United States came from the National Institutes of Health (NIH) in 2003 and required researchers applying for direct annual costs of $500,000 or more to create a plan for sharing their research data.\(^1\) While this policy applied to a very limited number of grants awarded by the NIH, not including most R01 grants,\(^2\) it was a clear indication that data is an important product of research that must be cared for, shared, and curated. Yet, the 2008 NIH Public Access Policy, which applied mainly to research articles, did not expand upon data as a research object to be shared.\(^3\)

Then in 2011, the National Science Foundation (NSF) followed the NIH in adopting a data policy. This policy directed that all grant applications include a two-page-maximum data management plan (DMP) describing how the researchers would maintain, preserve, and make their data available.\(^4\) The NSF specified that this supplemental documentation must include the types of data and other materials collected, applicable standards, provisions for sharing and providing access to the data for reuse, and plans for archiving the data.\(^5\) More immediately impactful than the NIH policy, this policy meant that NSF grants with poor DMPs could be rejected, although the policy did not specify follow-up procedures for directorates to ensure compliance. Although the general policy applies
across the entire National Science Foundation, different divisions and directorates within the NSF could each provide more extensive policies and guidance for their individual programs. For example, the NSF Engineering Directorate required DMPs to specify the period of data retention, with a minimum requirement of three years, and the Geological Sciences Directorate Division of Ocean Sciences stated that researchers must submit their data to an appropriate data center no later than two years after data collection. The NSF policy was the inducement for many libraries to begin creating data services, not only around consulting on data management plans but also around directly curating research data to satisfy both the data preservation and sharing portions of a DMP.

The NIH and NSF policies, while applying to a considerable number of researchers, were not systemic to the US federal funding system. That change came in 2013 when the White House Office of Science and Technology Policy (OSTP) published a memorandum on public access. The OSTP memo covered not only public access to publications based on government-funded research, but also directed agencies with over $100 million in annual research and development expenditures to require data management plans and maximize access to data from funded projects. Further, a White House Executive Order issued later in Spring 2013 required agencies to release their agency-generated data freely and in a machine-readable format, expanding the federal commitment to open and shared data. As of early 2016, many of the covered funding agencies have enacted new requirements in response to the OSTP memo while others have only preliminary plans for compliance.

Requirements for data management plans and data curation and sharing are not limited to the United States. The 2007 OECD “Principles and Guidelines for Access to Research Data from Public Funding” was instrumental in bringing together thirty countries under the goal of improved access to research data. Since then, significant work has been done, such as the Horizon 2020 program out of the European Commission, and additional examples from the United Kingdom and Canada highlighted here.

The Research Councils United Kingdom (RCUK) and Wellcome Trust in the United Kingdom have enacted several data requirements. These policies encourage researchers to make their data openly available as quickly as possible with a minimum number of restrictions. Similar to the US National Science Foundation, individual councils under the RCUK are also issuing their own data policies. The Engineering and Physical Sciences Research Council (EPSRC) is particularly notable in that the policy places heavy responsibility on the research organization—not just the researcher—for compliance. The policy dictates that organizations must make data openly available for a minimum of ten years with effective data curation across the data life cycle. A more complete list of UK funder and institutional policies is available from the Digital Curation Centre.
Canada is also developing data management policies for federally funded research. In 2015, three major Canadian research agencies—the Canadian Institutes of Health Research (CIHR), the Natural Sciences and Engineering Research Council of Canada (NSERC), and the Social Sciences and Humanities Research Council of Canada (SSHRC)—put out a draft statement on principles of data management.16 This draft policy builds on the Canadian government’s “Action Plan on Open Government,” which supports maximizing access to federally funded research and echoes funder policies from other countries by calling for data management plans and open data sharing.17 The draft policy notably establishes the different responsibilities of researchers, research communities, institutions, and funders.

Beyond federal governments, an emerging trend among nonprofit funders is toward the requirement for data management plans and data preservation and sharing. Private nonprofit funding agencies, such as the Bill and Melinda Gates Foundation, are adopting such mandates.18 The Gates Foundation policy was seen as an especially strong funder policy when it was announced in 2014 as it required immediate and open access to all data from all funded grants.19 The following year, the Ford Foundation adopted a policy requiring all data from its sponsored grants be made available with a Creative Commons Attribution License (CC BY 4.0),20 demonstrating funder interest not only in data sharing but also in allowing reuse and attribution. A major benefit of these data-sharing policies is that they require researchers to focus on better curation and management practices throughout the research process, knowing the data must be released at the end of a project.

For libraries engaged in grant writing and research, the US Institute of Museum and Library Services (IMLS) requires data sharing. The general guidelines for grants issued after December 2014 state, “If you collect and analyze data as part of an IMLS funded project, IMLS expects you to deposit data resulting from IMLS-funded research in a broadly accessible repository that allows the public to use the data without charge no later than the date upon which you submit your final report to IMLS. You should deposit the data in a machine-readable, non-proprietary digital format to maximize search, retrieval, and analysis.”21

The impetus behind funding agencies developing research data policies varies.22 Altruistically, the goal is to expand access to research and increase the speed and replicability of science. Another argument is to allow taxpayers access to the research that they have funded. Additionally, facing increasing budget constraints, the agencies are focused on avoiding duplicative research and gaining a full return on their funding investment through data reuse in other projects. Funding agencies also may be looking to expand the possibility of their funded research being commercialized, available to the developing world or outside of academia, and improving education.
Institutional Data Policies

With the increasing focus on data in the research and funding processes, individual academic institutions are creating and clarifying policies that outline data governance for their associated researchers. While many of these policies are more broadly concerned with intellectual property—a historic interest for universities with research resulting in patents—more research universities are starting to create stand-alone data policies. The 2013 ACRL SPEC Kit on research data management provides several examples of institutional data policies, and a more recent review of 206 major research universities in the United States found that almost half had some policy covering research data—either an IP (15%) or a stand-alone data policy (29%).

In contrast with funding agency data policies, university policies are often concerned with data ownership, retention, and access. For example, many policies describe what should happen to the research data when the researcher leaves the institution and who is allowed access to this data in the meantime. Data ownership, when explicit in the policy, is often given to the university; this is likely a by-product of the funding system in the United States, where grants are given to the university to administer (with subsequent university compliance requirements) instead of to the researcher directly.

Institutional policies are not yet universal, and there is often discrepancy between existing institutional policies, which may exceed the differences observed between funder policies. While some policies are clear and comprehensive, others may impede the ability for researchers to conduct research and collaborate with their peers.

Exemplar institutional data policies should cover research data ownership, stewardship, and expectations as well as provide clear definitions, identify access and ownership claims to the data, specify retention periods, and lay out the responsibilities of all data stakeholders (including what happens if a researcher leaves the institution). Due to local differences, the ideal policy contents will vary between institutions and countries.

There are several institutional policies that we recommend for review: the University of New Hampshire, the University of Minnesota, and the University of Massachusetts. These policies feature clear, explicit, and thorough language about what researchers should and should not do with their data. For example, the University of New Hampshire’s “Policy on Ownership, Management, and Sharing of Research Data” provides straightforward definitions for investigators, research, research data, ownership, custodianship, and stewardship. It acknowledges the authority of the investigators to do their own research, provides clear inclusion and exclusion of what constitutes research data, and defines roles and authority between the university administration and the investigator. Likewise, the “Research Data Management: Archiving, Ownership, Retention, Security,
Storage, and Transfer Policy” at the University of Minnesota is an example of direct writing. The policy provides details on ownership and stewardship, data retention and archiving, research data transfer, researcher obligations, and data security. Specifically, this policy defines the role of the university libraries under the extensive responsibilities section with a number of specific examples. The “Policy on Data Ownership, Retention, and Access” at the University of Massachusetts Amherst also provides detailed definitions and covers data ownership, custody, quality, retention, and access. Of particular note is the statement “When a collaboration comes to an end, and data was created during the collaboration, each member of the collaboration shall retain access to that data.”

More general guidance on developing a research data management policy is provided by the Association of Southeastern Research Libraries in collaboration with the Southeastern Universities Research Association. The model policy is intended to be comprehensive, allowing institutions to select and adapt relevant sections as appropriate. The model includes suggested statements on the purpose of the policy, data ownership, stakeholders and their responsibilities, and potential related institutional policies.

There are a variety of motivations for institutions to develop data policies. For example, universities have an interest in promoting and preserving the reputation of the institution and the researcher: where good data is known to be a product of the institution and its researchers, both entities can gain recognition for the data and research generated. Good policies may also prevent reputational damage when data is missing, lost, or found to be fraudulent. Another goal of an institutional data policy is to improve opportunities for commercialization, as controlling access to data and maintaining good data preservation and documentation are integral to patent applications. Finally, universities have a specific goal of data retention for educational reuse, as data is frequently shared between faculty and students in a “gift” culture that introduces students and early career researchers to the field. Overall, however, institutional data policy is frequently focused on control of research data, which is sometimes at odds with mandates to curate this data for sharing with others.

Journal Data Policies

Journal data policies add further complexity to the data policy landscape. These policies align with some of the recent changes to funding agency policies by pushing for greater access to research data. While still not ubiquitous in scholarly publishing, there are increasing journal and publisher requirements for researchers to make the supporting data available alongside the published journal article.

The actual journal requirements for data sharing fall on a spectrum from strict to loose. The Public Library of Science (PLOS) family of journals caused
controversy in 2014 for being one of the first large journals to strictly require
data availability as a condition of publication.\(^{33}\) Other journals, such as *Science*
and *Nature*, expected researchers who published within their pages to provide
data as requested but did not explicitly require data to be made openly available
at the time of publication.\(^{34}\) A further trend is data journals, where only the
data with some supporting metadata is submitted for peer review.\(^{35}\) We should
be aware that journals in our own field are starting to enact similar expecta-
tions, such as for the *Journal of Librarianship and Scholarly Communication* (*JLSC*).\(^{36}\)

Beyond the basic expectation that data be made available, journals often
recommend places for researchers to place their data to be in compliance with the
policy. For journals with loose sharing expectations, it is often enough to simply
provide access to the data when contacted rather than placing the data in a spe-
cific repository. For journals with strict data requirements, the journal may rec-
ommend a specific repository for data deposit, such as *JLSC’s* recommendation
of its Dataverse instance,\(^ {37}\) or provide a list of recommended repositories across a
variety of disciplines and subdisciplines.\(^ {38}\) Local institutional repositories run by
libraries often do not appear in these directories or are listed with qualifications
when they are.\(^ {39}\) Overall, journal policies reinforce the new data-sharing require-
ments of funder data policies and often take them a step further by specifying the
preferred data repository for hosting.

Journals have their own motivations for enacting data policies. The princi-
pal incentive is to increase the reproducibility of the articles these journals pub-
lish. Greater scrutiny of research data can prevent the publication of problematic
research and ensure that any subsequent retractions are easier to identify and
resolve, both of which improve the quality and reputation of a journal. Open-ac-
cess journals also have an altruistic motivation to expand their open mission into
the data realm.

**Navigating the Data Policy Landscape for Curation**

Libraries undertaking data curation must be aware of funding agency, institu-
tional, and journal data policies as these policies can directly affect local curation
practices. Part of this awareness requires the ability to navigate the variances that
frequently exist between the policy types. Thankfully, there are also a few areas of
policy agreement that can further strengthen curation efforts.

With respect to policy agreement, both funder and institutional policies of-
ten include a requirement about data retention after the end of project. This
is a direct response to the fact that researchers often have difficulty with data
retention, with Vines and colleagues finding that research data availability falls by approximately 17 percent per year after the paper is published due to the data becoming "either lost or on inaccessible storage." Having a mandated policy on retention provides leverage when working with researchers, who often think of retention in terms of long-term storage instead of involving the preservation actions necessary to make sure that the data remains usable in the future. By relying on the policies, we can ensure that data remains not only available but usable well after a project is complete.

However, while funder and institutional data policies often include retention mandates, retention times can sometimes conflict. The minimum retention period for data from government-funded research, per the US Office of Management and Budget (OMB) Uniform Guidance, is three years after the completion of the grant. Where data retention times are stated in university policy, they can often be three, five, or seven years, or a fixed time may not be specified. Retention periods may also vary by discipline. This creates confusion for researchers in how long they actually need to retain data and whose policy takes precedence. In practice, longer retention times are preferred, especially in light of a two recent retractions of six- and eight-year-old papers where the original data could not be located to address concerns about the research. Retention is unfortunately more complicated for sensitive data; in this case, it may be best to refer questions to the local institutional review board (IRB), the institution’s chief information officer, or similar IT representatives to determine local practice. In general, libraries should recommend that stated retention times be treated as minimums, with a preference for longer, but not indefinite, retention periods.

A second area of overlap between institutional and funder policies is that responsibility for the data often falls to both the researcher and the university. US funding agency policy places sharing and retention responsibility on the principal investigator (PI) of the grant in addition to mandating compliance measures from the university overall. Institutional policy, on the other hand, often designates the PI as the data steward who makes most of the decisions about the data while the university is the actual data owner. This further varies by institution and disciplinary practices. In general, the institution is held responsible for the compliance of its researchers and has a financial interest in meeting these requirements. In terms of data curation efforts, these shared responsibilities lend authority to libraries to preserve data on behalf of the university and its commitments, as libraries are a natural home for this type of work.

There is a downside to this overlap, as the university will not often exert its claim of data ownership under local policy unless extreme measures are involved. These measures can include researcher misconduct, avoiding sensitive data breaches and large-scale audits, and issues when prestigious research is in-
Involvolved or where the university has a large financial stake in the research or research products, in addition to routine compliance requirements from funders. The 2015 court case between the University of California–San Diego (UCSD) and the University of Southern California (USC) illustrates such an example. UCSD sued USC and former UCSD researcher Paul Aisen for attempts to cut UCSD off from grant money and the longitudinal data from the Alzheimer's Disease Cooperative Study when the PI, Aisen, tried to move the center and many of its researchers from UCSD to USC. In this case, UCSD used its backing from the NIH, which awarded the grant to UCSD and wished to continue to do so, and its data ownership policy to block Aisen and USC from their attempts to transfer the research project. While many researchers have likely left UCSD in possession of their data and grant funding, the prestige and value of this research prompted UCSD to exert its claim to research via its data policy. As research funding becomes more competitive, such issues are likely to arise more frequently.

These ownership issues may be further complicated in the case of unfunded research, collaborative research, or research where there is not a sole primary investigator at one institution. Researchers may want to share their data but feel confused when policy is not clear about external collaborative data sharing but still requires institutional ownership of the data.

Journal data policies deviate from funder and institutional policy in this area in that they rarely identify institutions as having any role at all in policy compliance. This is evident by how infrequently institutional repositories show up in lists of recommended repositories and the qualifications upon them, such as minting DataCite DOIs and placing data in an external backup repository, when they do. It is useful to be aware of these external requirements when developing repository services as well as actively promoting institutional repositories to journals as a way to satisfy their data-sharing requirements. An example of this promotion comes from a group of data librarians and curators called DataCure who in 2015 called upon PLOS to include institutional repositories as a recommended place for archiving data.

Most often, funding agency, institutional, and journal data policies disagree because the three policy types have fundamentally different intents. Funding agencies are usually concerned with data management, preservation, and sharing as they seek to prevent duplication and improve return on investment. In contrast, institutional data policies are more focused on data ownership and data control as they seek to maintain reputation and commercial control of intellectual property. Journal data policies, on the other hand, aim to improve the reproducibility of the journal’s published articles by providing access to the corresponding data. All policy types aim to lengthen the life cycle of research data, but two do so by promoting openness and while the third does so by putting restrictions on the data. While the OECD Principles, OSTP Memo, and
Canadian council policies demonstrate the emerging standardization of data policies across the major government funding agencies, no similar motion has yet occurred for institutional and journal data policies. Therefore, libraries engaging in data curation have a role in developing institutional data policy where it does not exist and lobbying for the inclusion of local data repositories in current and future journal data policies.

Another challenge to curation is that the three policy types have different enforcement mechanisms. Funding agencies have more leverage here as they can withhold money from those institutions that do not comply. Universities seldom have this option for enforcement. Journals can either refuse to publish articles by noncompliant researchers or retract them later. Additionally, many researchers may not think to look to their libraries for support, and libraries rarely have the authority to enforce improved data curation practices, which compounds these curation problems. Libraries involved in data curation should consider other motivations for researcher participation in data curation besides direct compliance.

Finally, one of the biggest challenges comes from when policies are diametrically opposed. The question then becomes: which policy wins? There is no clear answer to this question at present, so local practice may vary as institutions continue to develop data curation policies and services. Libraries, however, already support researchers in evaluating journals for publishing and can apply that skill set here, holding a key position from which to identify where policies conflict and to collaborate with administrators, researchers, and journal editors to resolve the effects of disparate policies on data curation.

Navigating this shifting policy landscape can be a challenge for libraries working to curate research data. There are, however, many things that libraries can do in this area:

- Identify opportunities for the library to act on behalf of the institution and its obligations to preserve and retain data.
- Advocate locally that the library is a natural home for these tasks, which might not get accomplished without the library’s leadership.
- Collaborate with institutional administrators to either develop or improve institutional data policies.
- Be proactive in advocating the library’s role in compliance with journal editors.
- Leverage existing policies to promote services.
- Provide guidance to researchers on complying with (sometimes conflicting) policy requirements.

There is no one best way to navigate the changing policy landscape, but by being aware of the myriad requirements, libraries can use them to the best advantage.
Summary

Libraries engaged with data curation must be knowledgeable about the funding agency, institutional, and journal data policies that influence researcher responsibilities. Awareness of these evolving policies will enhance the library services for research data curation. We also have the opportunity to influence development or modification of our institutional policies to improve local data curation practices. Future navigation of policies will be important until further clarity and harmonization are established between funding agencies, institutions, and journals.
