1 Introduction

Several models in phase transitions give rise to geometric equations relating the normal velocity of the interface to its curvature. The curvature term is related to surface tension and the surface energy is often an anisotropic function of the normal direction, indicating the preferred directions of the underlying crystal structure.

When the surface energy is isotropic, the resulting equation is the mean curvature flow and a variety of techniques have been used to analyze this flow. Gage & Hamilton [15] and Grayson [20] showed that a smooth planar embedded curve first becomes convex and then smoothly shrinks to a point in finite time. Huisken [23] generalized this result showing that any convex set, in any space dimension, shrinks to a point smoothly. However, in general, in dimensions higher than two, embedded hypersurfaces may develop singularities and a weak formulation of the mean curvature flow is necessary to define the subsequent evolution after the onset of singularities. Brakke [9] was the first to study the mean curvature flow past the singularities. Using varifolds in geometric measure theory, he constructed global generalized solutions that are not necessarily unique. Almgren, Taylor & Wang [2] used a time-step energy minimization approach together with geometric measure theory to analyze a very general class of equations.

An alternate approach, initially suggested in the physics literature by Ohta, Jasnow & Kawasaki [25], for numerical calculations by Sethian [27] and Osher & Sethian [26], represents the evolving surfaces as the level set of an auxiliary function solving an appropriate nonlinear differential equation. This level-set approach has been extensively developed by Chen, Giga & Goto [10] and Evans & Spruck [13]. Evolution of hypersurfaces with codimension greater than one is studied by Ambrosio & Soner [3], and intrinsic definitions were developed by Soner [28] and Barles, Soner & Souganidis [8]. Since the level set equations are degenerate parabolic, the theory of viscosity solutions by Crandall & Lions [12] is used to define the level set solutions. For more information on viscosity solutions see the survey by Crandall, Ishii & Lions [11] and the book by Fleming & Soner [14].

When the surface energy is convex, the evolution law is still degenerate parabolic and much of the above theory generalizes to these equations as well.

Non-smooth energies are also of interest, and an interesting class of surface energies - called crystalline energies - have level sets that are polygonal. For these energies, the corresponding solutions are also polygonal and the evolution law is a system of ordinary differential equations for the length of each side of the solution (see equations (2.3) below). An excellent introduction to
crystalline motion is given in the recent book of Gurtin [22] and in the surveys of Taylor [31] and Taylor, Cahn & Handwerker [33]. Short time existence and the other properties of the planar solutions are proved by Angenent & Gurtin [4, 5] and Taylor [32]. Almgren & Taylor [1] showed that the crystalline flow is consistent with the variational approach developed in [2]. In a recent preprint, Giga, Gurtin & Mathias [17] studies the classical solutions in three space dimensions and a deep viscosity theory for graph-like solutions of very general geometric equations have been developed by Giga & Giga [16] and the references therein.

In this paper, we consider a two dimensional problem with a crystalline energy whose level sets are regular n-polygons and show the convergence of these solutions to the unique smooth solution of the mean curvature flow. This convergence has already been proved by Girao [18] for convex solutions and by Girao & Kohn [19] for graph-like solutions. They also obtained the rate of convergence. Here we generalize their convergence result to general curves that are not necessarily convex. Our proof is a set theoretic analogue of the weak viscosity approach of Barles & Perthame [6, 7]. To describe our approach, let \( \{\Omega_n(t)\}_{t \in [0,T)} \) be a sequence of open polygons each solving a crystalline flow. We define two possible limits

\[
\bar{\Omega}(t) := \limsup_{n \to \infty, s \to t} \Omega_n(s), \\
\underline{\Omega}(t) := \liminf_{n \to \infty, s \to t} \Omega_n(s),
\]

(precise definitions are given in (4.2) below). Then, with only \( L^\infty \) estimates, the Barles-Perthame approach enables us to show that \( \bar{\Omega} \) is a viscosity subsolution of the mean curvature flow, and \( \underline{\Omega} \) is a viscosity supersolution of the mean curvature flow. Since, in two space dimensions, there is a smooth solution to the mean curvature flow, we show that both of these sets are equal to the smooth solution. This yields the convergence of \( \Omega_n \) in the Hausdorff topology.

The paper is organized as follows: in the next section, we give the definition of crystalline motion and prove the existence of a regular solution in §3. We define the weak viscosity limits in §4 and prove their viscosity properties. Convergence is proved in the final section. Some properties of the viscosity solutions are gathered in Appendix.
2 Crystalline motion and n-smooth polygons.

Here we recall several standard definitions and equations. Gurtin’s book [22] provides an excellent introduction to this subject. Also, see [30, 32].

2.1 Surface energy

All geometric flows that we consider are, formally, the gradient flows of the surface energy functional

\[(2.1) \quad I(\Gamma) := \int_{\Gamma} f(\vec{n}) \, ds,\]

where \(\Gamma\) is a Jordan curve in \(\mathbb{R}^2\), \(\vec{n}\) is its outward unit normal vector and \(f : S^1 \rightarrow [0, \infty)\) is the surface energy function. It is customary to extend \(f\) to the whole \(\mathbb{R}^2\) as a homogenous of degree one function:

\[f(x) = |x|f \left( \frac{x}{|x|} \right), \quad \forall x \neq 0,\]

and define

\[\hat{f}(\theta) := f(\cos \theta, \sin \theta).\]

Then the twice differentiability of \(f\), on \(\mathbb{R}^2 \setminus \{0\}\), is equivalent to the twice differentiability of \(\hat{f}\), and \(f\) is convex if and only if \(\hat{f}(\theta) + \hat{f}_\theta(\theta) \geq 0\) for all \(\theta\).

The Frank diagram of the surface energy \(f\) is simply the polar graph of \(\hat{f}^{-1}\) or, equivalently, it is the one-level set of \(f\), i.e.,

\[\mathcal{F}(f) := \{x \in \mathbb{R}^2 : f(x) = 1\} = \{r(\cos \theta, \sin \theta) : r\hat{f}(\theta) = 1\}.\]

When the surface tension \(f\) is smooth and convex, the gradient flow for the functional \(I\) has the form:

\[(2.2) \quad \beta(\theta)V = (\hat{f}(\theta) + \hat{f}_\theta(\theta)) \kappa,\]

where \(V\), \(\kappa\), \((\cos \theta, \sin \theta)\) are, respectively, the normal velocity, the curvature, and the normal vector of the solution \(\Gamma(t)\), and the given non-negative function \(\beta\) is the kinetic coefficient. The mean curvature flow corresponds to \(\hat{f} \equiv \beta \equiv 1\), and the other cases with strictly convex surface energy are qualitatively very similar to the mean curvature flow.

If \(f\) is not convex, we need to modify both \(f\) and \(\beta\) to obtain the correct relaxed equation. This relaxation procedure and the analytical properties of the relaxed equation was studied by Gurtin, Soner & Souganidis [21] and, independently, by Ohnuma & Sato [24]. The common critical hypothesis in these works is the continuous differentiability of the relaxed surface energy function.
2.2 Crystalline flow

Non-smooth energy functions are of interest in models for crystal growth, as it is well known that solid crystals can exist in polygonal shapes. An interesting class of non-smooth energies are the crystalline energies. The Frank diagram of crystalline energies are polygons.

Although the crystalline energies are only Lipschitz continuous, an appropriate weak formulation of (2.2) is possible and is called the crystalline flow; see [22, §12.5] for the precise definition. The crystalline flow was derived by Taylor [30] and, independently, from thermodynamical considerations by Angenent & Gurtin [4].

Consider a crystalline energy function $f$ and let $\Theta := \{\theta_1, \ldots, \theta_N\}$ be the angles corresponding to the corner points of the Frank diagram of $f$. Suppose that the curve $\Gamma$ is locally smooth around a point with a normal angle $\theta^* \notin \Theta$, say $\theta^* \in (\theta_1, \theta_2)$. We can, then, decrease the energy $I(\Gamma)$ of $\Gamma$, by infinitesimally alternating the normal angle between $\theta_1$ and $\theta_2$. Therefore, for crystalline energies, we only consider polygonal solutions with normal angles taking values in $\Theta$.

In this paper, for simplicity, we only consider crystalline energies whose Frank diagrams are regular $n$-polygons, and kinetic coefficient $\beta = 1$. Then

$$\Theta = \Theta_n := \left\{ \frac{2\pi k}{n} : k = 0, 1, \ldots, (n - 1) \right\}$$

and the evolution of side $i$, $L_i(t)$, is governed by

$$(2.3) \quad V_i(t) = -\frac{2\tan(\pi/n)}{l_i(t)} \chi_i,$$

where $V_i(t)$, $l_i(t)$, and $\chi_i$, are, respectively, the normal velocity, the length, and the discrete curvature of $L_i(t)$. The discrete curvature $\chi_i \in \{-1, 0, +1\}$ and it is equal to $+1$ if both edges of $L_i(t)$ have positive curvature, and it is equal to $-1$ if both edges of $L_i(t)$ have negative curvature, and it is equal to zero otherwise; see figure 1.

We close this subsection by stating the evolution rule for the length, $l_i(t)$, of the sides of a solution of the crystalline flow:

$$(2.4) \quad \frac{d}{dt} l_i(t) = \frac{1}{\cos^2(\pi/n)} \left( 2\cos(2\pi/n) \frac{\chi_i^2}{l_i(t)} - \frac{\chi_{i+1}^2}{l_{i+1}(t)} - \frac{\chi_{i-1}^2}{l_{i-1}(t)} \right).$$

This equation follows from (2.3) and geometry; see [22, (12.39)].
2.3 \( n \)-smooth polygons

We continue by defining the notion of a “good” solutions of (2.3). For a polygon \( \Gamma \), let \( N(\Gamma) \) be the total number of sides.

**Definition 2.1** We say that a closed polygon \( \Gamma \) is \( n \)-smooth, if \( N(\Gamma) \) is finite and

1. \( \Gamma \) encloses a simply-connected, bounded, open subset of \( \mathbb{R}^2 \),
2. for every \( i = 1, \ldots, N(\Gamma) \), the normal angle \( \theta_i \) of the side \( i \) belongs to \( \Theta_n \),
3. \( \theta_i - \theta_{i-1} = 2\pi/n, \) for every \( i = 1, \ldots, N(\Gamma) \).

The third condition is formally equivalent to the “discrete continuity” of the normal angle, which explains the term “smooth”.

By definition, any solution of (2.3) satisfies the second condition.

Let

\[
N^+(\Gamma) := \left\{ i \in \{1, \ldots, N(\Gamma)\} : \chi_i = 1 \right\},
\]

\[
N^-(\Gamma) := \left\{ i \in \{1, \ldots, N(\Gamma)\} : \chi_i = -1 \right\},
\]

\[
N^0(\Gamma) := \left\{ i \in \{1, \ldots, N(\Gamma)\} : \chi_i = 0 \right\}.
\]

Then for any \( n \)-smooth polygon \( \Gamma \),

\[
N^+(\Gamma) - N^-(\Gamma) = \sum_{i=1}^{N(\Gamma)} \chi_i = n,
\]
is an identity which is the discrete version of
\[ \int_C \kappa \, ds = 2\pi, \]
for a smooth Jordan curve \( C \).

3 Regularity.

In this section, we will show that there is a unique \( n \)-smooth solution of (2.3) which evolves smoothly in time (i.e. remains \( n \)-smooth) and shrinks to a point in finite time. This is the discrete analogue of a theorem of Grayson [20] and Gage & Hamilton [15]. A more general statement is proved by Taylor [32, Theorem 3.1]. For reader’s convenience, we provide all the details of this result.

**Theorem 3.1 (Taylor [32])** Let \( \Gamma_0 \) be an \( n \)-smooth polygon enclosing an open set \( Q_0 \). Then there exist \( n \)-smooth polygons \( \{ \Gamma(t) \}_{t \in [0,T)} \) solving (2.3) with the initial condition \( \Gamma(0) = \Gamma_0 \). Moreover \( \Gamma(t) \) shrinks to a point, as \( t \uparrow T \), and

\[
T = \frac{|Q_0|}{2n \tan(\pi/n)}.
\]

**Remark 3.2** Uniqueness follows from Gurtin [22, §12] and Taylor [32].

We start with several results towards the proof of Theorem 3.1.

Clearly, for a short time there is a solution \( \Gamma(t) \) satisfying initial data. Let \( t_1 > 0 \) be the first time this solution is no longer \( n \)-smooth. Since, by definition, the normal angles of any solution take values in \( \Theta_n \) (c.f. §2.2), there are two possibilities at \( t_1 \): either the length of one or more sides tend to zero, or the solution self-intersects at \( t_1 \). We will first show that the latter does not happen. Our proof is very similar to [32, Theorem 3.2(1)].

**Lemma 3.3** Let \( t_1 \) and \( \{ \Gamma(t) = \partial Q(t) \}_{t \in [0,t_1]} \) be as above. Then
\[
\lim \inf_{t \to t_1} \inf \{ l_i(s) : s \in [0,t], i = 1, \ldots, N(\Gamma(0)) \} = 0.
\]

**Proof.** Suppose to the contrary. Then,
\[
\inf \{ l_i(s) : s \in [0,t_1], i = 1, \ldots, N(\Gamma(0)) \} > 0.
\]
Then, by (2.4), each \( \ell_i(\cdot) \) is smooth in \((0, t_1)\) and therefore

\[
\Omega(t_1) = \lim_{t \to t_1} \Omega(t)
\]
exists in the Hausdorff topology. By the definition of \( t_1 \), \( \Gamma(t_1) \) self-intersects. Moreover, for all \( t \in [0, t_1] \),

\[
|\theta_i - \theta_{i-1}| = \frac{2\pi}{n}, \quad i = 1, \ldots, N(\Gamma(t)) = N(\Gamma(0)),
\]
so that at \( t_1 \) there are two possibilities: either two sides or two corner points touch each other. Note that, by (3.2), if a corner point touches a side, then necessarily two sides also touch each other.

**Case 1.** Suppose that \( \ell_i(t_1) \) intersects at \( \ell_j(t_1) \).

Then, a straightforward analysis argument shows that \( (x_i, x_j) = (1, -1) \) or \( (x_i, x_j) = (-1, 1) \). Since the analysis of both cases are symmetric, we may assume \( (x_i, x_j) = (1, -1) \). Then, \( \ell_i(t_1) \leq \ell_j(t_1) \).

**Subcase (1).** \( \ell_i(t_1) < \ell_j(t_1) \).

Then for some \( \delta > 0 \), \( \ell_i(t) < \ell_j(t) \) in \((t_1 - \delta, t_1] \), and therefore,

\[
\alpha(t) := \frac{2 \tan(\pi/n)}{\ell_j(t)} - \frac{2 \tan(\pi/n)}{\ell_i(t)} > 0 \quad t \in (t_1 - \delta, t_1].
\]

But \( \alpha(t) \) is equal to the time derivative of the distance between \( \ell_i(t) \) and \( \ell_j(t) \) and this distance is equal to zero at \( t_1 \). Hence this case is not possible.

**Subcase (2).** \( \ell_i(t_1) = \ell_j(t_1) \).

Then, the sides adjacent to \( \ell_i(t) \) and \( \ell_j(t) \) also touch each other at time \( t_1 \), and therefore, there has to be two sides satisfying the assumptions of the previous subcase, thus yielding a contradiction.

**Case 2.** Two corner points touch each other.

Let the intersection, \( x_i(t) \) of \( \ell_i(t) \) and \( \ell_{i+1}(t) \) be the same as the intersection \( x_j(t) \) of the sides \( \ell_{j-1}(t) \) and \( \ell_j(t) \). Then the angle between \( \ell_{i+1}(t) \) and \( \ell_j(t) \) and the one between \( \ell_i(t) \) and \( \ell_{j-1}(t) \) are equal to \( 2\pi/n \). By rotation, we may assume that \( \ell_i(t) \) and \( \ell_j(t) \) are parallel to the \( x \)-axis, and \( \ell_{i+1}(t) \) is aligned with the \( \ell_{j-1}(t) \) (c.f. Figure 2). Moreover, \( \chi_k \geq 0 \) for \( k = i, i + 1, j, j - 1 \). Let \( V_{x_i}(t) \) and \( V_{x_j}(t) \) be the velocity vectors of the points \( x_i(t) \) and \( x_j(t) \), respectively. Then,

\[
(0, 1) \cdot (V_{x_j} - V_{x_i}) \geq 0,
\]

and the inequality is strict unless \( \chi_k = 0 \) for all \( k = i, i + 1, j, j - 1 \). Since \( x_i(t_1) = x_j(t_1) \), we conclude that \( \chi_k = 0 \) for all \( k = i, i + 1, j, j - 1 \). But, then, \( V_{x_i}(t) = V_{x_j}(t) = 0 \) and this contradicts with the definition of \( t_1 \).\[\square\]
Our next result is

**Lemma 3.4** Let \( t_1 \) and \( \{\Gamma(t) = \partial \Omega(t)\}_{t \in [0, t)} \) be as above. Suppose \( t_1 \) is strictly less than the extinction time. Then as \( t \to t_1 \), \( \Omega(t) \) converges to an \( n \)-smooth polygon \( \Omega(t_1) \) in the Hausdorff topology.

**Proof.** By the previous lemma, there is a side \( i^* \) such that

\[
\liminf_{t \to t_1} l_{i^*}(t) = 0.
\]

The main step in this proof is to show \( \chi_{i^*} = 0 \). So we suppose that it is equal to \( +1 \) or \( -1 \). Since the analysis of both cases are similar, we may assume that \( \chi_{i^*} = 1 \). Set \( \theta = 2\pi/n \).

1. In this step we will show that \( l_{i^*}(t) \) is continuous on \([0, t_1]\). For future references, we will show that, for any \( j \), \( l_j(\cdot) \) is continuous on \([0, t_1]\). By (2.4), all sides remain bounded and we set

\[
B := \limsup_{t \to t_1} l_j(t).
\]

Suppose that

\[
B > \liminf_{t \to t_1} l_j(t) := A.
\]

Since \( l_j(\cdot) \) is continuous in \([0, t_1]\), it crosses \((A + B)/2\) infinitely many times before \( t_1 \). In particular, by the mean value theorem, there is a sequence \( t_n \uparrow t_1 \) such that

\[
l_j(t_n) \geq \frac{A + B}{2}, \quad \lim_{n \to +\infty} l'_j(t_n) = +\infty.
\]

However, by (2.4),

\[
l'_j(t_n) \leq \frac{2\cos \theta}{l_j(t_n) \cos^2(\theta/2)} \leq C,
\]

for some constant \( C \) independent of \( n \). Hence \( A = B \).
2. The step, closely follows [32, Proposition 3.1].

Since \( t_1 \) is strictly less than the extinction time, there are at least two sides which have non-zero length at time \( t_1 \). Hence there are two sides \( L_{p_0} \) and \( L_{p_1} \) such that \( p_0 < i^* < p_1 \), \( l_{p_0}(t) \) and \( l_{p_1}(t) \) are uniformly positive in \((0, t_1)\) and

\[
\lim_{t \to t_1} l_j(t) = 0, \quad \forall j = p_0 + 1, \ldots, p_1 - 1.
\]

For any \( j \), let \( L_j(t) \) be the line extending \( L_j(t) \), \( x_{j+1}(t) \) be the intersection between \( L_j(t) \) and \( L_{j+1}(t) \) and \( \theta_j \) be the angle between the outward normal and the horizontal axis. Then, as \( t \uparrow t_1 \), all \( x_{p_0+1}(t), \ldots, x_{q}(t) \) converge to the same point \( x^* \).

We analyze several cases separately.

**Case 1.** \( \chi_j \neq 0 \) for all \( j = p_0 + 1, \ldots, p_1 - 1 \).

Since we have assumed that \( \chi_{i^*} = 1, \chi_j = 1 \) for all \( j = p_0 + 1, \ldots, p_1 - 1 \) and

\[
x^* \in \bigcap_{0 \leq t < t_1} \bigcap_{j = p_0}^{p_1} \{ y \in \mathbb{R}^2 : (y - x_j(t)) \cdot (\cos \theta_j, \sin \theta_j) \leq 0 \}.
\]

By geometry, \( |\theta_{p_0} - \theta_{p_1}| \leq \pi \).

**Subcase 1.** \( |\theta_{p_0} - \theta_{p_1}| < \pi \).

Let \( y(t) \) be the intersection between \( L_{p_0}(t) \) and \( L_{p_1}(t) \). We define

\[
d(t) = (y(t) - x^*) \cdot (\cos \theta_{p_0+1}, \sin \theta_{p_0+1}), \\
d_{p_0+1}(t) = \text{dist}(x^*, L_{p_0+1}(t)).
\]

Then \( d_{p_0+1}(t) \leq d(t) \) for all \( t \in [0, t_1) \) and \( d_{p_0+1}(t_1) = d(t_1) = 0 \). Moreover, \( d(t) \) is Lipschitz continuous in \( t \) and

\[
\frac{d}{dt} d_{p_0+1}(t) = -V_{p_0+1}(t) = \frac{2 \tan(\theta/2)}{l_{p_0+1}(t)}.
\]

Hence,

\[
0 \leq \int_t^{t_1} \frac{2 \tan(\theta/2)}{l_{p_0+1}(\tau)} d\tau = d_{p_0+1}(t) \leq d(t) \leq \|d\|(t_1 - t) \quad \forall t < t_1.
\]

This contradicts the fact \( l_{p_0+1}(t) \to 0 \) as \( t \uparrow t_1 \).

**Subcase 2.** \( |\theta_{p_0} - \theta_{q}| = \pi \).

We repeat the argument used in the previous case with

\[
\tilde{d}(t) = \text{dist}(L_{p_0}(t), L_{p_1}(t)), \\
\tilde{d}_{p_0+1}(t) = \text{dist}(L_{p_0+1}(t), L_{p_1}(t)).
\]
Case 2. $\chi_q = 0$ exactly for one $q \in \{p_0 + 1, \ldots, p_1 - 1\}$.

Then, $\chi_j = 1$ for $j = p_0 + 1, \ldots, q - 1$ and $\chi_j = -1$ for $j = q + 1, \ldots, p_1 - 1$, or $\chi_j = -1$ for $j = p_0 + 1, \ldots, q - 1$ and $\chi_j = 1$ for $j = q + 1, \ldots, p_1 - 1$. Since the arguments in both cases are similar, without loss of generality, we only consider the first possibility.

If $|\theta_{p_0} - \theta_q| \leq \pi$, we argue as in Case 1, using side $L_q(t)$ instead of $L_{p_1}(t)$. We also argue similarly, when $|\theta_q - \theta_{p_1}| \leq \pi$. Therefore we may assume that $|\theta_{p_0} - \theta_q| > \pi$ and that there is a side $L_j(t)$ with $q < j < p_1$, which is parallel to $L_{p_0}(t)$. Let $\mathcal{L}$ be the line going through $x^*$ and parallel to both $L_{p_0}(t)$ and $L_j(t)$. Set

$$d(t) = \text{dist}(L_{p_0}(t), \mathcal{L}) - \text{dist}(L_j(t), \mathcal{L}).$$

Then $d(t_1) = 0$ and since $|\theta_{p_0} - \theta_q| > \pi$, $d(t) > 0$ for all $(0, t_1)$: see Figure 3.

However, this contradicts the fact that $d'(t) > 0$ for all $t$ sufficiently close to $t_1$.

Case 3. $\chi_j = 0$ for more than one side.

Suppose that $\chi_q$ and $\chi_j$ are equal to zero. Then $x^*$ belongs to both $L_q(t)$ and $L_j(t)$ for all $t$, and therefore, $j = q - 1$ or $q + 1$. Since $l_q(t)$ converges to zero, at least one side adjacent to $L_q(t)$ has non-zero discrete curvature. Hence there are two sides with zero discrete curvature and they are adjacent to each other. As in Case 1, all the other sides between $L_{p_0}(t)$ and $L_{p_1}(t)$ satisfy $\chi_k = 1$ and we argue as in Case 1.

Therefore the case $\chi_i^* = 1$ is not possible. An entirely similar argument shows that the case $\chi_i^* = -1$ is not possible neither. Hence $\chi_i^* = 0$ and $L_{i^* - 1}$ and $L_{i^* + 1}$ are parallel and the normal angle of the "new" side is equal to that of these two ones.

We are now in a position to prove Theorem 3.1.

Proof of Theorem 3.1.
Since $\Gamma(0)$ is $n$-smooth, for short time, there is an $n$-smooth solution $\Gamma(t)$. Moreover, by Lemma 3.4, this solution remains $n$-smooth until one side of $\Gamma(t)$ vanishes. Let $t_1$ be the first time a side vanishes. Then, $\Gamma(t)$ is $n$-smooth and $N(\Gamma(t)) = N(\Gamma(0))$ for all $t \in [0, t_1)$. By Lemma 3.3, $\Gamma(t_1)$ is also $n$-smooth and $N(\Gamma(t_1)) \leq N(\Gamma(0)) - 2$. We repeat this procedure starting from $\Gamma(t_1)$. Since $N(\Gamma(0))$ is finite, we have only to repeat finitely many times.

Let $t_1 < t_2 < \ldots < t_N$ be the times at which a side vanishes. Let $t_N > 0$ be the time when $N^{-}(\Gamma(t_N)) = N^{0}(\Gamma(t_N)) = 0$. Then, by (2.5), $N^{+}(\Gamma(t_N)) = n$ and $\Gamma(t)$ is convex for all $t \geq t_N$.

We see that $\Gamma(t)$ shrinks to a point at finite time. Indeed, by (2.5), we can calculate the rate of change of $|\Omega(t)|$:

$$
\frac{d}{dt} |\Omega(t)| = \sum_i V_i l_i \\
= - \sum_{i \in N^{+}(\Gamma(t))} 2 \tan \frac{\pi}{n} + \sum_{i \in N^{-}(\Gamma(t))} 2 \tan \frac{\pi}{n} \\
= -2n \tan \frac{\pi}{n}.
$$

From the foregoing calculation, we conclude that the solution shrinks to a point at some time $T$. Moreover, at time $T$

$$
0 = |\Omega(T)| = |\Omega_0| - 2n \tan \frac{\pi}{n} \cdot T,
$$

and (3.1) follows. \hfill \Box

4 Weak Viscosity Limits.

In this section, we will study the properties of the set-theoretic analogue of the weak viscosity limits of Barles & Perthame [6, 7]. Let $\{\Gamma_n(t)\}_{t \in [0,T]}$ be a sequence of $n$-smooth solutions of (2.3), and let $\Omega_n(t)$ be the open set enclosed by $\Gamma_n(t)$. Assume that there is a constant $R > 0$, independent of $n$, satisfying

$$
\Omega_n(t) \subset B(0, R), \tag{4.1}
$$

where $B(x, r) = \{ y \in \mathbb{R}^2 : |y - x| \leq r \}$. Following [7, 28], for $t \in [0, T)$, we define

$$
\tilde{\Omega}(t) := \bigcap_{s > t, R \geq 1} \text{cl} \left( \bigcup_{T_n \geq R} (0, s \leq T) \Omega_n(s) \right), \tag{4.2}
$$

\hfill 11
\[
\Omega(t) := \bigcup_{r > 0, N \geq 1} \text{int} \left( \bigcap_{0 \leq s < T} \Omega_n(s) \right) ,
\]

where cl \( A \) and int \( A \) are, respectively, the closure and the interior of the set \( A \). In view of (4.1), \( \Omega(t) \) is a bounded closed set and \( \Omega(t) \) is a bounded open set. We will show that, respectively, \( \Omega(t) \) is a weak subsolution and \( \Omega(t) \) is a weak supersolution of the mean curvature flow.

This type of stability results are typical in the theory of viscosity solutions and, in general, they are a simple consequence of the maximum principle. However, the crystalline flow is not defined for smooth curves and this fact is the major difficulty in the following analysis.

The notion of viscosity solutions we use is first introduced by the second author in [28] and further developed in [8, 29]. Here we only recall the definition; other relevant definitions and results are gathered in Appendix.

We continue by recalling several definitions that will be used in the subsequent analysis. For subsets \( \{\Omega(t)\}_{0 \leq t < T} \) in \( \mathcal{R}^2 \), the upper semi-continuous envelope (u.s.c.) and, respectively, the lower semi-continuous envelope (l.s.c.) are defined by

\[
\Omega^*(t) = \bigcap_{r > 0} \text{cl} \left( \bigcup_{0 \leq s < T} \Omega(s) \right) , \quad \Omega_*(t) = \bigcup_{r > 0} \text{int} \left( \bigcap_{0 \leq s < T} \Omega(s) \right) , \quad t \in [0, T).
\]

Then, it is clear that \( (\Omega)_* = \Omega \) and \( (\Omega^*)_* = \Omega \). For other properties of these envelopes, see [28, Lemma 3.1].

For a collection of closed subsets \( \{O(t)\}_{0 \leq t < T} \) with smooth boundary, \( V_O(x, t) \) is the normal velocity of \( \partial O(t) \) at \( x \) and \( \kappa_O(x, t) \) is the curvature of \( \partial O(t) \) at \( x \). We use the convention that the curvature of a convex curve is non-negative.

We are now in a position to give the weak (viscosity) definition of the mean curvature flow we will use. This definition is very similar to the one given in [28]; see Appendix for the connection between these two definitions.

**Definition.** Let \( \{\Omega(t)\}_{0 \leq t < T} \) be a collection of bounded subsets in \( \mathcal{R}^2 \) satisfying \( \Omega_*(t) \neq \emptyset \) for every \( t \in [0, T) \).

We say \( \{\Omega(t)\}_{0 \leq t < T} \) is a weak subsolution of the mean curvature flow, if for any closed, smooth subsets \( \{O(t)\}_{0 \leq t < T} \),

\[
V_O(x_0, t_0) \leq -\kappa_O(x_0, t_0), \tag{4.3}
\]

at each \( t_0 \in (0, T) \) and \( x_0 \in \partial O(t_0) \) satisfying,

\[
\Omega^*(t) \subset O(t) \quad \forall t \neq t_0, \tag{4.4}
\]
\( \Omega^*(t_0) \subset O(t_0), \quad \partial \Omega^*(t_0) \cap \partial O(t_0) = \{x_0\} \). 

Similarly, we say \( \{\Omega(t)\}_{0 \leq t < T} \) is a weak supersolution of the mean curvature flow, if for any closed, smooth subsets \( \{O(t)\}_{0 \leq t < T} \),

\[
V_O(x_0, t_0) \geq -\kappa_O(x_0, t_0),
\]
at each \( t_0 \in (0, T) \) and \( x_0 \in \partial O(t_0) \) satisfying,

\[
O(t) \subset \Omega_*(t) \forall t \neq t_0, \quad O(t_0) \subset \Omega_*(t_0), \quad \partial \Omega_*(t_0) \cap \partial O(t_0) = \{x_0\}.
\]

Condition (4.4) implies that \( (x_0, t_0) \in \partial O(t_0) \times (0, T) \) is the strict maximizer of \(-\text{dist}(x, \partial \Omega_*(t))\) over all \((x, t) \in \partial O(t) \times (0, T)\). A similar conclusion also holds for supersolutions.

Following is the set theoretic analogue of the Barles & Perthame procedure [6, 7], [14, §5], and it is the chief technical contribution of this paper.

Recall that \( T_n(t) = d_n(t) \).

Lemma 4.1 \( \hat{\Omega} \) is a weak subsolution of the mean curvature flow, while \( \Omega \) is a weak supersolution.

Before we give the proof of this lemma, we will first give a formal proof of the subsolution property.

In view of our definition of a weak solution, we start with smooth sets \( \{O(t)\}_{0 < t < T} \) and a point \((x_0, t_0)\) satisfying (4.4). Our goal is to verify (4.3). By (4.4) there are a subsequence \( n_k \) and a sequence \((x_k, t_k) \rightarrow (x_0, t_0)\) satisfying \( \Omega_{n_k}(t_k) \subset O(t_k) \) and that \( x_k \in \Gamma_{n_k}(t_k) \). Although there are several other cases, assume that \( x_k \) is the intersection of \( L_{i-1}(t_k) \) and \( L_i(t_k) \) of \( \Gamma_{n_k}(t_k) \), and \( \chi_i = \chi_{i-1} = 1 \). We choose a coordinate system so that \( x_k \) is the origin and the \( L_i(t_k) \) side is included in the \( x_1 \)-axis. Let \( n_1 = (0, 1), \) \( n_2 = (\sin(2\pi/n_k), \cos(2\pi/n_k)) \). Then, the unit normal vector of \( \partial O \) satisfies \( n_O(x_k, t_k) = (\sin \alpha, \cos \alpha) \) for some \( 0 < \alpha < 2\pi/n_k \). By the crystalline equation (2.3),

\[
\begin{align*}
V_{x_k} \cdot n_1 &= V_i = \frac{2 \tan(\pi/n_k)}{l_i}, \\
V_{x_k} \cdot n_2 &= V_{i-1} = \frac{2 \tan(\pi/n_k)}{l_{i-1}},
\end{align*}
\]

and therefore,

\[
V_{x_k} = 2 \tan \frac{\pi}{n_k} \left( \frac{1}{\tan(2\pi/n_k)} \left( \frac{1}{l_i} - \frac{1}{l_{i-1}} \right), -\frac{1}{l_i} \right),
\]

(4.5)
\begin{equation}
V_O(x_k, t_k) = V_{x_k} \cdot n_O(x_k, t_k) = - \frac{1}{\cos^2(\pi/n_k)} \left( \frac{\sin(2\pi/n_k - \alpha)}{l_i} + \frac{\sin \alpha}{l_{i-1}} \right).
\end{equation}

Since \( V_O(x_k, t_k) < 0 \), we may assume \( \inf_{k \in \mathbb{N}} \kappa_O(x_k, t_k) > 0 \). This implies that, as \( k \to \infty \), both \( l_i \) and \( l_{i-1} \) converge to zero. By elementary geometry, we obtain a sharper estimate: for every \( \varepsilon > 0 \),
\[
l_i \leq \frac{2 \sin \alpha}{\kappa_O(x_k, t_k) - \varepsilon}, \quad l_{i-1} \leq \frac{2 \sin(2\pi/n_k - \alpha)}{\kappa_O(x_k, t_k) - \varepsilon},
\]
for sufficiently large \( k \). Substitute these into (4.6):
\[
V_O(x_k, t_k) \leq - \frac{\kappa_O(x_k, t_k) - \varepsilon}{2 \cos^2(\pi/n_k)} \left( \frac{\sin(2\pi/n_k - \alpha)}{\sin \alpha} + \frac{\sin \alpha}{\sin(2\pi/n_k - \alpha)} \right)
\leq - \kappa_O(x_k, t_k) + \varepsilon.
\]

In the foregoing argument, we crucially used the assumption that \( x_k \) is a "convex" corner point of \( \Gamma_{n_k} \). Although this is the most likely situation, other cases may also arise, and for that we will perturb the test sets \( O \) in the preceding proof.

**Proof.** We will only prove the subsolution property. Proof of the supersolution case is similar.

Let \( \{O(t)\}_{0 < t < T} \) and \((t_0, x_0)\) be as in (4.4). Our goal is to verify (4.3), i.e.,
\[
v := V_O(x_0, t_0) \leq -\kappa := -\kappa_O(x_0, t_0).
\]

If necessary, by perturbing \( O(\cdot) \), we may assume that \( \kappa \neq 0 \). We analyze two cases separately:

**Case 1.** \( \kappa > 0 \). 

For \( \varepsilon > 0 \), \( x^* \in \mathcal{R}^2 \) and a large constant \( K \), let \( D^\varepsilon(t : x^*) \) be the disk with center \( x^* \) and radius
\[
R^\varepsilon(t) = \frac{1}{\kappa - \varepsilon} + v(t - t_0) + K(t - t_0)^2.
\]

Set
\[
x_0^\varepsilon := x_0 - R^\varepsilon(t_0)n_O(x_0, t_0).
\]

By the smoothness of \( \partial O \), for all sufficiently large \( K \), there is a \( \delta^\varepsilon \) such that
\begin{equation}
O(t) \cap B(x_0, 2\delta^\varepsilon) \subset D^\varepsilon(t : x_0^\varepsilon) \cap B(x_0, 2\delta^\varepsilon),
\end{equation}

14
for all $|t - t_0| \leq 2\delta^\epsilon$. We fix $K$ large enough, so that the above inequality holds.

Next we approximate $D^\epsilon(t : x^*)$ by regions with polygonal boundaries. Let

$$C_n := \{ x \in \mathbb{R}^2 : x \cdot (\cos(\frac{2l\pi}{n}), \sin(\frac{2l\pi}{n})) \leq 1, \quad \forall l = 0, 1, \ldots, (n - 1) \},$$

and, for any $x^*$, set

$$D_n^\epsilon(t : x^*) := \{ x^* \} \cup R_n^\epsilon(t) C_n.$$ 

Since $D_n^\epsilon(\cdot : x_0^*)$ approximates $D^\epsilon(\cdot : x_0^*)$, by (4.4) and (4.7), there are a subsequence $n_k$ and sequences $(x_k, t_k) \to (x_0, t_0)$, $y_k \to x_0^\epsilon$ satisfying:

$$x_k \in \Gamma_{n_k}(t_k) \cap \partial D_{n_k}^\epsilon(t : y_k),$$

$$\Omega_{n_k}(t) \cap B(x_0, \delta^\epsilon) \subset D_{n_k}^\epsilon(t : y_k) \cap B(x_0, \delta^\epsilon), \quad \forall |t - t_0| \leq \delta^\epsilon.$$ 

A proof of this fact is given in Appendix; Lemma 6.2. To simplify the notations, we assume that $n_k = k$ and write $D_k(t)$ for $D_{n_k}^\epsilon(t : y_k)$.

Let $x_k$ be on the $i$-th side of $\Gamma_k(t_k)$. Then, the normal velocity, $V_i$, of this side is equal to the normal velocity of $D_k$ at $t_k$. Hence,

$$V_i = v + 2K(t_k - t_0)$$

Since $D_k(t_k)$ is a regular $k$-polygon, $\chi_i(t_k) = 1$ and, therefore, the length, $l_i(t_k)$, of side $i$ of $\Gamma_k(t_k)$ is less than or equal to the length of any side of $D_k(t_k)$:

$$l_i(t_k) \leq 2R^\epsilon(t_k) \sin \frac{\pi}{k}.$$ 

Then, by (2.3) and the foregoing discussion,

$$v + 2K(t_k - t_0) = V_i = \frac{-2\tan(\pi/k)}{l_i(t_k)} \leq -\frac{1}{R^\epsilon(t_k) \cos(\pi/k)}.$$ 

Since $R^\epsilon(t_k)$ converges to $1/\kappa$ and $t_k \to t_0$, we obtain (4.3) by first letting $k \to \infty$ and then $\epsilon \downarrow 0$.

**Case 2.** $\kappa < 0$.

For small $\epsilon > 0$ and any $x^*$, let $x_0^\epsilon := x_0 + R^\epsilon(t_0)n_\partial(x_0, t_0)$ and let $D^\epsilon(t : x^*)$ be the complement of the disk with center $x^*$, radius

$$R^\epsilon(t) = \frac{1}{-\kappa + \epsilon} + v(t - t_0) - K(t - t_0)^2.$$ 

As in the previous case, there is a $\delta^\epsilon$ such that

$$O(t) \cap B(x_0, 2\delta^\epsilon) \subset D^\epsilon(t : x_0^\epsilon) \cap B(x_0, 2\delta^\epsilon),$$

(4.8)
for all \(|t - t_0| \leq 2\delta^\varepsilon\), and for any \(x^*\), we set

\[
D_n(t : x^*) := \mathcal{R}^2 \setminus \{x^*\} \oplus R^\varepsilon(t)C_n.
\]

Then, \(D_n^\varepsilon(\cdot : x_0)\) approximates \(D^\varepsilon(\cdot : x_0)\) and, by (4.4) and (4.8), there are a subsequence \(n_k\), and sequences \((x_k, t_k) \to (x_0, t_0), y_k \to x_0^\varepsilon\) satisfying:

\[
x_k \in \Gamma_{n_k}(t_k) \cap \partial D_{n_k}^\varepsilon(t_k : y_k),
\]

\[
\Omega_{n_k}(t) \cap B(x_0, \delta^\varepsilon) \subset D_{n_k}^\varepsilon(t : y_k) \cap B(x_0, \delta^\varepsilon), \quad \forall |t - t_0| \leq \delta^\varepsilon.
\]

Again, we assume that \(n_k = k\), write \(D_k(t)\) for \(D_{nk}^\varepsilon(t : y_k)\), and let \(x_k\) belong to the \(i\)-th side of \(\Gamma_k(t_k)\). Since, in this case, the normal velocity of \(D_k\) at \(t_k\) is equal to \(v - 2K(t_k - t_0)\),

\[
V_i = v - 2K(t_k - t_0).
\]

If \(v \leq 0\), (4.3) is immediately satisfied. Hence, we may assume that \(v > 0\). So, for small \(\varepsilon > 0\), \(V_i > 0\) and, by (2.3), \(\chi_i = -1\). Consequently, \(l_i(t_k)\) is greater than or equal to the length of any side of \(D_k(t_k)\):

\[
l_i(t_k) \geq 2R^\varepsilon(t_k) \sin \frac{\pi}{k},
\]

and therefore,

\[
v - 2K(t_k - t_0) = V_i = \frac{2 \tan(\pi/k)}{l_i(t_k)} \leq \frac{1}{R^\varepsilon(t_k) \cos(\pi/k)}.
\]

We first let \(k \to \infty\) and then \(\varepsilon \downarrow 0\). Since \(R^\varepsilon(t_k)\) converges to \(1/|\kappa| = -1/\kappa\), the result is (4.3).

\[
\square
\]

5 Convergence.

Let \(\Gamma_0 = \partial \Omega_0\) be a twice differentiable Jordan curve and \(\Gamma_{n_0} = \partial \Omega_{n_0}\) be an \(n\)-smooth approximation of \(\Gamma_0\) satisfying

\[
\lim_{n \to \infty} d_H(\Omega_{n_0}, \Omega_0) = 0,
\]

where \(d_H\) is the Hausdorff distance. For each \(n\), there is a unique \(n\)-smooth solution \(\{\Gamma_n(t)\}_{t \in [0,T_n]}\) of (2.3) satisfying the initial condition \(\Gamma_n(0) = \Gamma_{n_0}\) by Theorem 3.1. Moreover,
Let $\Omega$ and $\Omega_0$ be as in §4 so that, by construction,

\begin{equation}
\text{(5.3)} \quad \text{cl} \Omega(t) \subset \Omega(t), \quad \forall t \in [0, T_0).
\end{equation}

Moreover, $\Omega$ is a weak subsolution of the mean curvature flow, and $\Omega_0$ is a weak supersolution of the mean curvature flow. In general space dimension, there is no comparison between weak sub- and supersolutions, however, in dimension two, there is always a smooth solution of the mean curvature flow, $\Gamma(t) = \partial \Omega(t)$ and we will show that,

\begin{equation}
\text{(5.4)} \quad \Omega(t) \subset \text{cl} \Omega(t) \subset \text{cl} \Omega(t), \quad \forall t \in [0, T_0).
\end{equation}

Combining (5.3) and (5.4), we will then obtain the convergence of $\Omega_n$ to $\Omega$ in Hausdorff topology, thus generalizing the previous convergence results of Girao and Kohn & Girao [19, 18].

The foregoing outline of our convergence result is entirely analogous to the Barles & Perthame procedure of proving convergence with very weak $L^\infty$ estimates [6, 7].

**Theorem 5.1** Let $\Gamma_n(t) = \partial \Omega_n(t)$ be the solution of (2.3) with initial data $\Gamma_{n,0}$, and let $\Gamma(t) = \partial \Omega(t)$ be the smooth solution of the mean curvature flow with initial data $\Omega_0$. Assume (5.1), then

\begin{equation}
\text{(5.5)} \quad \lim_{n \to \infty} d_H(\Omega_n(t), \Omega(t)) = 0,
\end{equation}

locally uniformly in $t \in [0, T_0)$.

We begin with

**Lemma 5.2** $\Omega(0) \subset \text{cl} \Omega_0 \subset \text{cl} \Omega(0)$.

**Proof.** We will only prove the first inclusion. Proof of the second inclusion is similar.

Since $d_H(\Omega_n, \Omega_0) \to 0$, for any $x_0 \in \Omega_0$ there are $\delta_0 > 0$ and $n_0 \in \mathcal{N}$ satisfying

$$B(x_0, \delta_0) \subset \subset \Omega_n \quad \forall n > n_0.$$ 

Let $\gamma_n$ be the regular $n$-polygon enclosing $B(x_0, \delta_0)$. If necessary, by taking $n_0$ larger, we may assume that $\gamma_n \subset \subset \Omega_n$ for all $n > n_0$. Let $\gamma(t)$ be the
solution of the crystalline flow (2.3) with initial data \( \gamma_n(0) = \gamma_n \) and \( \omega_n(t) \) be the open set enclosed by \( \gamma_n(t) \). Then, by the containment principle for crystalline motions (cf. Gurtin [22, §12]),

\[
B(x_0, \delta_0/2) \subset \omega_n(t) \subset \Omega_n(t) \quad \forall n > n_0, \ 0 \leq t \leq \frac{1}{4} \delta_0^2.
\]

Let \( n \to +\infty \) and \( t \downarrow 0 \) to conclude that \( B(x_0, \delta_0/2) \subset \Omega(0) \) and therefore \( x_0 \in \Omega(0) \).

In our second step, we will show that the smooth mean curvature flow yields a viscosity sub- and super-solution of the following equation:

\[
u_t + F(Du, D^2u) = 0 \quad \mathcal{R}^2 \times (0, T),
\]

where

(5.6) \[
F(p, X) = -\text{tr}((I - \bar{p} \otimes \bar{p})X)
\]

and \( \bar{p} = p/|p| \). This step is very similar to Ambrosio & Soner [3, §3].

Let \( \{\Gamma(t)\}_{0 \leq t < T_0} \) be a unique smooth mean curvature flow satisfying \( \Gamma(0) = \Gamma_0 \) and let \( d(x, t) \) be the signed distance function to \( \Gamma(t) \), i.e.,

\[
d(x, t) = \begin{cases} 
\text{dist}(x, \Gamma(t)) & \text{if } x \in \Omega(t), \\
-\text{dist}(x, \Gamma(t)) & \text{otherwise},
\end{cases}
\]

where \( \Omega(t) \) is the open set enclosed by \( \Gamma(t) \). For a scalar \( d \), \( d \wedge 0 = \min\{d, 0\} \) and \( d \vee 0 = \max\{d, 0\} \).

**Lemma 5.3** For any \( \delta > 0 \), there are constants \( \sigma = \sigma(\delta) > 0 \) and \( K = K(\delta) > 0 \) so that the function \( u(x, t) := e^{-K\int([d \vee 0](x, t) \wedge \sigma]} \) is a viscosity subsolution of

\[
u_t + F(Du, D^2u) = 0 \quad \text{in } \mathcal{R}^2 \times (0, T_0).
\]

**Proof.** For \( \delta > 0 \), there exists a \( \sigma = \sigma(\delta) > 0 \) such that \( d \) is smooth in \( \{x \in \mathcal{R}^2 : |d(x, t)| < 2\sigma\} \times [0, T_0 - \delta] \) and in this tubular set,

(5.7) \[
\Delta d(x, t) = \frac{\kappa(y, t)}{1 - \kappa(y, t)d(x, t)},
\]

where \( y \in \Gamma(t) \) is a unique point satisfying \( |d(x, t)| = |x - y| \) and \( \kappa(y, t) \) is the curvature of \( \Gamma(t) \) at \( y \). Since \( \{\Gamma(t)\}_{0 \leq t < T_0} \) is a smooth mean curvature flow,

(5.8) \[
d_t - \Delta d = 0 \quad \text{in } \Gamma(t) \times (0, T_0).
\]

18
Since 
\[ C(\delta) := \sup \{ |\kappa(x, t)| : (x, t) \in \partial \Omega(t) \times [0, T_0 - \delta] \} < \infty, \]
by (5.7) and (5.8), \( d \) is a classical subsolution of 
\[ d_t - \Delta d - K d \leq 0 \quad \text{on} \quad \{ x : 0 \leq d(x, t) \leq 2\sigma \} \times (0, T_0 - \delta) \]
for some \( K \geq C(\delta) \). Since \( |Dd| = 1 \), \( d \) is also a classical subsolution of 
\[ d_t + F(Dd, D^2d) - K d = 0 \quad \text{on} \quad \{ x : 0 \leq d(x, t) \leq 2\sigma \} \times (0, T_0 - \delta). \]

Let \( h^\epsilon \) be a bounded smooth function satisfying: \( h^\epsilon(r) = 0 \) for \( r < 0 \), \( h^\epsilon(r) = \sigma \) for \( r \geq \sigma \), and, as \( \epsilon \to 0 \), \( h^\epsilon(r) \) converges to \( (r \vee 0) \wedge \sigma \). Since \( F \) is geometric, i.e., 
\[ F(\lambda p, \lambda A + \mu p \otimes p) = \lambda F(p, A), \quad \lambda, \mu \geq 0, \]
by calculus, we conclude that \( u^\epsilon = e^{-Kt}h^\epsilon(d) \) is a classical subsolution of 
\[ u_t^\epsilon + F(Du^\epsilon, D^2u^\epsilon) \leq 0, \quad \text{on} \quad \mathcal{R}^2 \times (0, T_0 - \delta]. \]

We now let \( \epsilon \downarrow 0, \delta \downarrow 0 \) and use the celebrated stability property of viscosity solutions. \( \quad \Box \)

An entirely similar argument yields

**Lemma 5.4** For any \( \delta > 0 \), there are constants \( \sigma = \sigma(\delta) > 0 \) and \( K = K(\delta) > 0 \) so that the function \( u(x, t) := e^{Kt}[(d \wedge 0)(x, t) \vee (-\sigma)] \) is a viscosity supersolution of 
\[ u_t + F(Du, D^2u) = 0 \quad \text{in} \quad \mathcal{R}^2 \times (0, T_0). \]

We are now in a position to complete

**the proof of Theorem 5.1.** For the notational convenience, we set \( \Omega_n(t) = \emptyset \) for all \( n > 1, \ t > T_n \). Let \( \bar{\Omega} \) and \( \Omega \) be as in \( \S 4 \), and let \( \bar{T}, T \) be, respectively, the extinction time of \( \bar{\Omega}(t) \) and \( \Omega(t) \). Set \( \bar{T} = \min\{ T, T_0, \bar{T} \} \).

By Lemma 5.3, \( u(x, t) = e^{-Kr}[(d \vee 0)(x, t) \wedge \sigma] \) is a viscosity subsolution of 
\[ u_t + F(Du, D^2u) = 0 \quad \text{in} \quad \mathcal{R}^2 \times (0, \bar{T} - \delta), \]
and by Lemma 4.1 and Proposition 6.1, \( v(x, t) = \text{dist}(x, R^2 \setminus \Omega(t)) \) is a viscosity supersolution of (5.9). Moreover, by Lemma 5.2, \( u(\cdot, 0) \leq v(\cdot, 0) \) in \( \mathcal{R}^2 \), and therefore the comparison principle for solutions of (5.9) (c.f. Chen, Giga & Goto [10], Evans & Spruck [13]) yields 
\[ u \leq v \quad \text{in} \quad \mathcal{R}^2 \times [0, \bar{T} - \delta). \]
We claim that this inequality implies that
\[ \Omega(t) \subset \Omega(t) \quad \forall t \in [0, \tilde{T} - \delta). \]
Indeed, for \( (x, t) \in \Omega(t) \times [0, \tilde{T} - \delta) \), \( 0 < u(x, t) \). Then, by the previous inequality, \( 0 < v(x, t) \) and, therefore, \( x \in \Omega(t) \).

Similarly, we show that \( \tilde{\Omega}(t) \subset \text{cl} \Omega(t) \) for all \( t \in [0, \tilde{T} - \delta) \) and then, we let \( \delta \to 0 \) to obtain (5.4) on \( [0, \tilde{T}) \).

A lengthy elementary argument shows that (5.4) is equivalent to (5.5). Hence, (5.5) holds on \( [0, \tilde{T}) \).

By (5.2) and the construction, \( \tilde{T} \leq \tilde{T} \leq T_0 \). The uniform convergence of \( \Omega_n \) to \( \Omega \) implies that \( \tilde{T} = T_0 \). \( \Box \)

6 Appendix.

In this section we gather several properties of the weak solutions.

Let \( \{\Omega_n(t)\}_{0 \leq t < T_n} \), \( \{\tilde{\Omega}(t)\}_{0 \leq t < T} \) and \( \{\Omega(t)\}_{0 \leq t < T} \) be as in §4, and let \( d_n(x, t) \) (resp., \( d(x, t) \) and \( d(x, t) \)) be the signed distance function for \( \{\Omega_n(t)\}_{0 \leq t < T_n} \) (resp., for \( \{\tilde{\Omega}(t)\}_{0 \leq t < T} \) and \( \{\Omega(t)\}_{0 \leq t < T} \)). Then, the definitions of \( \tilde{\Omega}(t) \) and \( \Omega(t) \), are equivalent to
\[
(\hat{d} \land 0)(x, t) = \limsup_{n \to +\infty} (d_n \land 0)(y, s), \\
(\hat{d} \lor 0)(x, t) = \liminf_{n \to +\infty} (d_n \lor 0)(y, s).
\]

The following weak regularity result in \( t \) follows from an attendant modification of [28, Lemma 7.3],
\[
\limsup_{y \to x, s \downarrow t} (\hat{d} \land 0)(y, s) = (\hat{d} \land 0)(x, t) \quad (x, t) \in \mathbb{R}^2 \times (0, T), \\
\liminf_{y \to x, s \downarrow t} (\hat{d} \lor 0)(y, s) = (\hat{d} \lor 0)(x, t) \quad (x, t) \in \mathbb{R}^2 \times (0, T).
\]
These identities and the techniques of [28, §14] yield the equivalence between the weak solutions defined in §4 and the distance solutions defined by the second author in [28]. Let \( F \) be as in (5.6).

**Proposition 6.1** \( \{\Omega(t)\}_{0 \leq t < T} \) is a weak subsolution of the mean curvature flow satisfying (6.1) if and only if \( d_{\Omega^*}(x, t) \land 0 \) is a viscosity subsolution of
\[
u_t + F(Du, D^2u) = 0 \quad \text{in} \quad \mathbb{R}^2 \times (0, T).
\]
\( \{\Omega(t)\}_{0 \leq t < T} \) is a weak supersolution of the mean curvature flow satisfying (6.2) if and only if \( d_n(x, t) \vee 0 \) is a viscosity supersolution of (6.3).

We close the appendix by proving an approximation result used in §4.

**Lemma 6.2** Let \( \{O(t)\}_{0 \leq t < T} \) be a family of closed smooth sets and let \( t_0 \in (0, T), x_0 \in \partial O(t_0) \) satisfy (4.4). Let \( D^\varepsilon(t) \) and \( D^\varepsilon_n(t : x^*) \) be the same sets as in the proof of Lemma 4.1. Assume that \( D^\varepsilon(t : x^*_0) \) satisfies (4.7). Then there is a subsequence \( n_k \) and sequences \( (x_k, t_k) \rightarrow (x_0, t_0), y_k \rightarrow x^*_0 \) as \( k \rightarrow +\infty \) satisfying

\[
\begin{align*}
x_k & \in \Gamma_{n_k}(t_k) \cap \partial D^\varepsilon_{n_k}(t_k : y_k), \\
\Omega_{n_k}(t) & \cap B(x_0, \delta^\varepsilon) \subset D^\varepsilon_{n_k}(t : y_k) \cap B(x_0, \delta^\varepsilon), \quad \forall \ |t - t_0| \leq \delta^\varepsilon.
\end{align*}
\]

**Proof.** Fix \( \varepsilon > 0 \) and recall \((\hat{\Omega}^*)^* = \hat{\Omega} \). Let \( d_n(x, t) \) be the signed distance to \( D^\varepsilon_n(t : x^*_0) \), \( d(x, t) \) be the signed distance to \( D^\varepsilon(t : x^*_0) \) and let

\[
\alpha_n := \inf_{|t - t_0| \leq \delta^\varepsilon} \inf \{d_n(x, t) : x \in \Omega_n(t) \cap B(x_0, \delta^\varepsilon)\}.
\]

Choose \( t_n \in [t_0 - \delta^\varepsilon, t_0 + \delta^\varepsilon] \), \( x_n \in \Omega_n(t_n) \cap B(x_0, \delta^\varepsilon) \) and \( w_n \in \partial D^\varepsilon_{n_k}(t_n : x^*_0) \) such that

\[
|w_n - x_n| = |\alpha_n|.
\]

Set

\[
y_n = x^\varepsilon_0 - (w_n - x_n),
\]

so that

\[
\Omega_n(t) \cap B(x_0, \delta^\varepsilon) \subset D^\varepsilon_{n_k}(t : y_n) \cap B(x_0, \delta^\varepsilon) \quad \forall \ |t - t_0| \leq \delta^\varepsilon.
\]

Since \( x_0 \in \hat{\Omega}(t_0) \), by the definition of \( \hat{\Omega} \), there are a subsequence \( n_k \) and sequences \( (z_k, s_k) \rightarrow (x_0, t_0) \) such that

\[
z_k \in \Omega_{n_k}(s_k).
\]

Then

\[
\limsup_{k \rightarrow \infty} \alpha_{n_k} \leq \limsup_{k \rightarrow \infty} d_{n_k}(z_k, s_k) = d(x_0, t_0) = 0.
\]

A similar argument, using (4.7), shows that \( \liminf \alpha_{n_k} \geq 0 \). Hence \( \alpha_{n_k} \rightarrow 0 \) and therefore, \( y_{n_k} \rightarrow x^*_0 \).

It remains to show that \( (x_{n_k}, t_{n_k}) \rightarrow (x_0, t_0) \). Suppose that on a further subsequence, denoted by \( n_k \) again,

\[
(x_{n_k}, t_{n_k}) \rightarrow (\bar{x}, \bar{t}) \in B(x_0, 2\delta^\varepsilon) \times [t_0 - \delta^\varepsilon, t_0 + \delta^\varepsilon].
\]

Since \( d_n \) converges to \( d \) uniformly,

\[
d(\bar{x}, \bar{t}) = \lim_{k \rightarrow \infty} \alpha_{n_k} = 0 \leq \lim_{k \rightarrow \infty} d_{n_k}(z_k, s_k) = d(x_0, t_0).
\]

Since \( (x_0, t_0) \) is the strict minimizer of \( d \), this implies that \( (\bar{x}, \bar{t}) = (x_0, t_0) \). \( \Box \)
