Let $U_1, U_2, \ldots, U_d$ be totally ordered sets and let $V$ be a set of $n$ $d$-dimensional vectors in $U_1 \times U_2 \times \cdots \times U_d$. A partial ordering is defined on $V$ in a natural way. We consider the problem of finding all maximal elements of $V$ with respect to the partial ordering. The computational complexity of the problem is defined to be the number of required comparisons of two components and is denoted by $C_d(n)$. It is trivial that $C_1(n) = n-1$ and $C_d(n) \leq o(n^2)$ for $d \geq 2$. Previous results are $C_d(n) \leq o(n \log_2 n)$ for $d = 2, 3$. In this paper, we show

1. $C_d(n) \leq o(n \log_2 n^{d-2})$ for $d \geq 4$,

2. $C_d(n) \geq \lceil \log_2 n \rceil$ for $d \geq 2$. 
1. INTRODUCTION

Let \( U_1, U_2, \ldots, U_d \) be totally ordered sets and let \( V \) be a set of \( n \) dimensional vectors in \( U_1 \times U_2 \times \cdots \times U_d \). Let \( x_i(v) \) denote the \( i \)th component of any vector \( v \). A partial ordering \( \preceq \) is defined on \( V \) in a natural way, that is, for \( v, u \in V \), \( v \preceq u \) if and only if \( x_i(v) \leq x_i(u) \) for all \( i = 1, \ldots, d \), where \( \leq_i \) is the total ordering on \( U_i \). (We shall also write \( \preceq \) for \( \leq_i \). The context should make clear the meaning of \( \preceq \).) We consider the problem of finding all maximal elements of \( V \). The computational complexity of the problem is defined to be

\[
C_d(n) = \min_{A} \max_{V} c_d(A, V)
\]

where \( c_d(A, V) \) is the number of comparisons used by any algorithm \( A \) on any such set \( V \). In other words, \( C_d(n) \) is the maximum number of comparisons used by the algorithm that solves the problem the fastest in the worst case. We are interested in obtaining the upper and lower bounds on \( C_d(n) \) for all \( d \).

If \( d = 1 \), \( V \) is a totally ordered set. It is obvious that

\[
C_1(n) = n - 1.
\]

If \( d > 1 \), \( V \) is a partially ordered set. It is not difficult to convince oneself that to find the maximal elements of a general partially ordered set, any algorithm requires order \( n^2 \) comparisons in the worst case. However, for the special partial ordering \( \preceq \) on \( V \), we can do better. Recently, Luccio and Preparata [1] have shown that

\[(1.1) \quad C_d(n) = O(n \log n) \quad \text{for } d = 2 \text{ and } 3.\]

(In this paper, all logarithms are to base 2 and all comparisons are between components of the vectors in \( V \).)
It remained an open problem to show whether such reduction is attainable for \( d \geq 4 \). In this paper, we prove

\[
(1.2) \quad C_d(n) \leq \Theta(n(\log n)^{d-2}) \quad \text{for} \quad d \geq 4,
\]

and

\[
(1.3) \quad C_d(n) \geq [\log n!] \quad \text{for} \quad d \geq 2.
\]

Since \( \log n! \) is about \( n \log n \), the bounds in (1.1) and (1.3) are sharp for \( d = 2 \) and 3, with respect to the magnitude of \( n \). It remains an open problem to show whether the bounds in (1.2) and (1.3) are sharp for \( d \geq 4 \).

In Section 2 we prove (1.3). In Section 3 we describe the basic recursive procedure for obtaining the upper bound in (1.2). This procedure leads to the problem of finding, from a given set, the elements which are not less than any element in another given set. Upper bounds on the number of comparisons for solving this problem are established by another recursive procedure, in the final section.
2. LOWER BOUND

Lemma 2.1

\[ C_{d-1}(n) \leq C_d(n) \text{ for } d \geq 2. \]

Proof

Let \( A_d \) denote an algorithm which finds the maxima of \( n \) \( d \)-dimensional vectors with at most \( C_d(n) \) comparisons. It suffices to show that an algorithm \( A_{d-1} \) can be constructed from \( A_d \) such that \( A_{d-1} \) finds the maxima of \( n \) \((d-1)\)-dimensional vectors and uses the same number of comparisons as \( A_d \) does. Let \( V_{d-1} \) be a set of \( n \) \((d-1)\)-dimensional vectors. Define a set \( V_d \) of \( n \) \( d \)-dimensional vectors by

\[ V_d = \{ (v_1, v_2, \ldots, v_{d-1}, v_d) \mid (v_1, \ldots, v_{d-1}) \in V_{d-1} \}. \]

Let \( A_{d-1} \) be constructed from \( A_d \) by replacing every comparison between the \( d \)th components of two vectors in the algorithm \( A_d \) by the comparison between the \((d-1)\)st components of the vectors. Then \( A_{d-1} \) and \( A_d \) will be same for the set \( V_d \). Since \( A_d \) finds the maxima of \( V_d \), so does \( A_{d-1} \). Observe that \((v_1, \ldots, v_{d-1}, v_d)\) is a maximum of \( V_d \) if and only if \((v_1, \ldots, v_{d-1})\) is a maximum of \( V_{d-1} \). Therefore \( A_{d-1} \) finds the maxima of \( V_{d-1} \). Furthermore, by the definition of \( A_{d-1} \), it is clear that \( A_d \) and \( A_{d-1} \) use the same number of comparisons. We have proven the lemma.

Let \( S(n) \) denote the maximum number of comparisons used by the algorithm that sorts \( n \) records the fastest in the worst case. We have the following

Lemma 2.2

\[ S(n) \leq C_2(n). \]
Proof

Consider any algorithm which finds the maxima of $n$ 2-dimensional vectors. Let $v_1, \ldots, v_n$ be 2-dimensional vectors such that for all $i$, $x_1(v_i)$ are distinct and for all $i, j$,

(2.1) \[ x_1(v_i) > x_1(v_j) \text{ if and only if } x_2(v_i) < x_2(v_j). \]

We apply the algorithm to the set $\{v_1, v_2, \ldots, v_n\}$.

For each $v_i$ the algorithm must determine whether $v_i$ is a maximal element or not. To prove $v_i$ is maximal the algorithm must establish the relationships that, for each $j \neq i$, either $x_1(v_i) > x_1(v_j)$ or $x_2(v_i) > x_2(v_j)$. By (2.1) we know that all $v_i$ are maximal elements. The algorithm must establish the relationships that either $x_1(v_i) > x_1(v_j)$ or $x_1(v_i) < x_1(v_j)$ between all pairs $(i, j)$. This implies the algorithm will sort $x_1(v_1), \ldots, x_1(v_n)$. Therefore, $S(n) = O(n)$. \[\]

It is well known (for example, see Knuth [2, §5.3.1]) that

\[ S(n) \geq \lceil \log n \rceil. \]

Therefore, by Lemmas 2.1 and 2.2, we have shown the following

Theorem 2.1

For any $d \geq 2$,

\[ C_d(n) \geq C_{d-1}(n) \geq \ldots \geq C_2(n) \geq \lceil \log n \rceil, \]

so that about $n \log n$ comparisons are needed for finding the maxima of $n d$-dimensional vectors in the worst case.
3. ALGORITHMS FOR FINDING THE MAXIMA OF A SET OF VECTORS

In this and the following sections we shall construct algorithms to achieve the upper bounds asserted in (1.2). In the rest of the paper, we assume that for any two vectors $u, v$ in $V$, $R$ or $S$, $x_i(u) \neq x_i(v)$ for all $i$. Under this assumption it will be easier to describe the ideas of the algorithms. The algorithms can be obviously modified if the assumption is removed (see [1]). Without loss of generality, we assume that $n = 2^r$ for some positive integer $r$, and that the elements of $V$ have been arranged as a sequence $v_1, \ldots, v_n$ so that

$$(3.1) \quad x_1(v_1) > x_1(v_2) > \ldots > x_1(v_n).$$

(Note that sorting takes $O(n \log n)$ comparisons.)

Like many other "fast" algorithms (e.g., FFT), our algorithms will first solve two subproblems and then combine the results of the subproblems. We shall first find $\tilde{R}$, the set of the maxima of $\{v_1, \ldots, v_{n/2}\}$ and $\tilde{S}$, the set of the maxima of $\{v_{n/2+1}, \ldots, v_n\}$. Observe that by (3.1) the elements of $\tilde{R}$ are also maximal elements of $V$, but the elements in $\tilde{S}$ are not necessarily maximal elements of $V$. In fact, an element in $\tilde{S}$ is a maximal element of $V$ if and only if it is not $\preceq$ any element in $\tilde{R}$. Therefore, we have the following algorithm:

**Algorithm 3.1**

We define a recursive procedure for finding the set $V_M$ of the maxima of $V = \{v_1, \ldots, v_n\}$. To find $V_M$, we find $\tilde{R}$, the set of the maxima of $\{v_1, \ldots, v_{n/2}\}$, find $\tilde{S}$, the set of the maxima of $\{v_{n/2+1}, \ldots, v_n\}$ and then find $\tilde{T}$, the set of elements in $\tilde{S}$ which are not $\preceq$ any element in $\tilde{R}$. Then set $V_M = \tilde{R} \cup \tilde{T}$. 

(Note that sorting takes $O(n \log n)$ comparisons.)
The number of comparisons required by Algorithm 3.1 depends on those required to find $\tilde{T}$. Define

$$C_d(r,s) = \min_{A} \max_{|R|=r, |S|=s} c_d(A,R,S)$$

where $R$ and $S$ are any sets consisting of $r$ and $s$, respectively, $d$-dimensional vectors, and $c_d(A,R,S)$ is the number of comparisons used by any algorithm $A$ for finding the elements in $S$ which are not $\leq$ any element in $R$. Hence $\tilde{T}$ can be found in $C_d(n/2,n/2)$ comparisons, since $|R|,|S| \leq n/2$. Observe, however, that because of the relation (3.1), for $u \in \tilde{R}, v \in \tilde{S}$, $u \geq v$ if and only if $x_i(u) \geq x_i(v)$ for $i = 2, \ldots, d$. To find $\tilde{T}$, first components of the vectors do not have to be considered. We end up with considering $(d-1)$-dimensional vectors. Hence $\tilde{T}$ can be found in $C_{d-1}(n/2,n/2)$ instead of $C_d(n/2,n/2)$ comparisons. Therefore, by Algorithm 3.1, we obtain the following recurrence relation on $C_d(n)$:

(3.2) $C_d(n) \leq 2C_d(n/2) + C_{d-1}(n/2,n/2)$.

In the following section, we shall show (Theorem 4.2) that

(3.3) $C_d(r,s) \leq (\alpha_d r + \beta_d s) (\log r)(\log s)^{d-3} + dr$

for $d \geq 3$, where $\alpha_d$ and $\beta_d$ are constants. By (3.3), we have

(3.4) $C_{d-1}(n/2,n/2) \leq O(n(\log n)^{d-3})$ for $d \geq 4$.

Therefore, from (3.2) and (3.4), we obtain the main result of the paper:

Theorem 3.1

$C_d(n) \leq O(n(\log n)^{d-2})$ for $d \geq 4$. 
4. UPPER BOUNDS ON $C_d(r,s)$

This section deals with the proof of the following result: For $d \geq 3$

$$(4.1) \quad C_d(r,s) \leq (\alpha_d r + \beta_d s)(\log r)(\log s)^{d-3} + dr.$$ 

We shall first prove (4.1) for $d = 3$ and then use induction on $d$ to prove (4.1) for all $d$. We shall first describe the key idea used in the induction.

Let $R$ and $S$ be two sets consisting of $r$ and $s$, respectively, $d$-dimensional vectors. Assume $d \geq 4$. Without loss of generality we assume that the elements of $R$ have been arranged as $u_1, \ldots, u_r$ and the elements of $S$ as $v_1, \ldots, v_s$ so that

$$(4.2) \quad x_1(u_1) > x_1(u_2) > \ldots > x_1(u_r),$$

$$(4.3) \quad x_1(v_1) > x_1(v_2) > \ldots > x_1(v_s).$$

Also, we assume that $s = 2^m$ for some positive integer $m$. Define $x_1(u_0) = \infty$ and $x_1(u_{r+1}) = -\infty$. Using binary search we find $k$, $0 \leq k \leq r$, such that

$$(4.3) \quad x_1(u_k) \geq x_1(v_{s/2}) > x_1(u_{k+1}).$$

We now divide $R$ into two subsets $R_1$ and $R_2$ such that $R_1 = \{u_i | 1 \leq i \leq k\}$ and $R_2 = \{u_i | k < i \leq r\}$. Also divide $S$ into two subsets $S_1$ and $S_2$ such that $S_1 = \{v_i | 1 \leq i \leq s/2\}$ and $S_2 = \{v_i | s/2 < i \leq s\}$. 
Recall that our problem is to find all elements in S which are not less than any element in R. We let $[R \ S]$ denote this problem. It is trivial to see that the problem $[R \ S]$ can be done by doing four subproblems, $[R_1 \ S_1]$, $[R_2 \ S_1]$, and $[R_2 \ S_2]$. Observe that the problem $[R_2 \ S_1]$ is trivial, since by (4.2) and (4.3) we know there is no element in $R_2$ which is greater than any element in $S_1$. Thus, we do not have to worry about the problem $[R_2 \ S_1]$. Furthermore, observe that by (4.2) and (4.3) the first component of any element in $R_1$ is greater than that of any element in $S_2$. Hence by the same reason as we used in the previous section, to do the problem $[R_1 \ S_2]$ we only have to consider $(d-1)$-dimensional vectors rather than d-dimensional vectors. Thus, to solve the problem $[R \ S]$ for d-dimensional vectors, we can instead solve the three subproblems:

1. the problem $[R_1 \ S_1]$ for d-dimensional vectors,
2. the problem $[R_2 \ S_2]$ for d-dimensional vectors,
3. the problem $[R_1 \ S_2]$ for $(d-1)$-dimensional vectors.
Therefore, we have shown

\[(4.4) \quad C_d(r, s) \leq C_d(k, s/2) + C_d(r-k, s/2) + C_{d-1}(k, s/2).\]

In the rest of the section we shall first prove (4.1) for \(d = 3\) then use (4.4) to prove (4.1) for general \(d\) by induction.

**Theorem 4.1**

\[C_3(r, s) \leq (\alpha_3 r + \beta_3 s) \log r\]

for constants \(\alpha_3\) and \(\beta_3\).

**Proof**

Let \(\{v_1, \ldots, v_s\}\) be the elements of \(S\). We establish the theorem by exhibiting an algorithm which is adapted from a result in [1].

**Algorithm 4.1**

This algorithm finds all elements in \(S\) which are not less than any element in \(R\) for \(d = 3\).

1. Arrange the elements of \(R\) as a sequence \(u_1, \ldots, u_r\) such that

\[x_1(u_1) > x_1(u_2) > \ldots > x_1(u_r).\]

2. Arrange the elements of \(S\) as a sequence \(v_1, \ldots, v_s\) such that if \(a(j)\) is the largest value of the index \(i\) such that \(x_1(u_i) \geq x_1(v_j)\) then

\[a(1) \leq a(2) \leq \ldots \leq a(s).\]

\((x_1(u_0)\) is defined to be \(x_1(v_s)\))

3. Set \(j \leftarrow 1\).
4. If \(a(j) = 0\), \(v_j\) is not less than any element in \(R\) and go to step 9.

5. Construct \(T(a(j))\), the set of maxima of \(\{(x_2(u_i), x_3(u_i)) | i = 1, \ldots, a(j)\}\), and arrange its elements as a sequence \(w_1, \ldots, w_v\) such that

\[x_2(w_1) > x_2(w_2) > \ldots > x_2(w_v)\]

6. If \(x_2(v_j) > x_2(w_1)\), \(v_j\) is not less than any element in \(R\) and go to step 9.

7. Determine the largest value \(i^*\) of the index \(i\) such that

\[x_2(w_i) \geq x_2(v_j)\] for \(w_i \in T(a(j))\).

8. If \(x_3(v_j) > x_2(w_{i^*})\), \(v_j\) is not less than any element in \(R\) and go to step 9.

9. If \(j < s\), \(j \leftarrow j+1\) and return to step 4.

10. Terminate the algorithm.

Step 5 can be efficiently performed by using, for example, an AVL binary tree \([2, \S 6.2.3]\) as the information structure which stores the elements of \(T(a(j))\). For details of this information structure and for the proof of the validity of the algorithm, see \([1]\). We now estimate the number of comparisons used in the algorithm. It is shown in \([1]\) that the total number of comparisons needed for step 5 is \(\leq O(r \log r)\). Clearly, step 1 also takes \(O(r \log r)\) comparisons. By using the binary search technique, steps 2 and 7 take \(O(s \log r)\) comparisons. Hence the total number of comparisons for the whole algorithm is \(O(r \log r) + O(s \log r)\).
Theorem 4.2

For $d \geq 3$,

$$C_d(r, s) \leq (\alpha_d r + \beta_d s) (\log r)(\log s)^{d-3} + dr,$$  \hspace{1cm} (4.5)

where $\alpha_d = \alpha_3 + 3 + 4 + \ldots + (d-1)$ and $\beta_d = 2^{-(d-3)} \beta_3$.

($\alpha_3, \beta_3$ are given by Theorem 4.1.)

Proof

We shall prove the theorem by induction on $d$. By Theorem 4.1, (4.5) holds for $d = 3$. Assume that (4.5) holds for $d = \ell - 1$. Without loss of generality, we assume that $s = 2^m$ for some positive integer $m$. Then we have

$$C_{\ell-1}(r, 2^m) \leq (\alpha_{\ell-1} r + \beta_{\ell-1} 2^m) (\log r)m^{\ell-4} + (\ell-1)r.$$  \hspace{1cm} (4.6)

By (4.4) we know that there exist $p_1 (= k/r)$ and $q_1 (= (r-k)/r)$ such that

$$C_{\ell}(r, 2^m) \leq C_{\ell}(p_1 r, 2^{m-1}) + C_{\ell}(q_1 r, 2^{m-1}) + C_{\ell-1}(p_1 r, 2^{m-1}).$$  \hspace{1cm} (4.7)

Note that

$$0 \leq p_1, q_1 \leq 1 \text{ and } p_1 + q_1 = 1.$$  \hspace{1cm} (4.8)

We shall use (4.6) and (4.7) to prove that

$$C_{\ell}(r, 2^m) \leq (\alpha_{\ell} r + \beta_{\ell} 2^m) (\log r)m^{\ell-3} + \ell r,$$

that is, (4.5) for $d = \ell$. The proof below is elementary but tedious. The essential idea is to apply (4.7) recursively. It is not difficult to see from (4.7) we can prove that
(4.9) \[ C_e(r, z_m) \leq \sum_{i_1=1}^{m} [C_e(A_{i_1}, \ldots, i_m, r, 1) + C_e(B_{i_1}, \ldots, i_m, r, 1)] \]

\[ + \sum_{j=1}^{m} \sum_{i_1=1}^{j} C_e(D_{i_1}, \ldots, i_j, r, z_m - j), \]

where \( A_{i_1}, \ldots, i_m \), \( B_{i_1}, \ldots, i_m \), and \( D_{i_1}, \ldots, i_j \) are defined as follows:

\[
\begin{cases}
A_{i_1}, \ldots, i_m = p_{i_1}, \ldots, i_m E_{i_1}, \ldots, i_m \\
B_{i_1}, \ldots, i_m = q_{i_1}, \ldots, i_m E_{i_1}, \ldots, i_m \\
D_{i_1}, \ldots, i_j = p_{i_1}, \ldots, i_j E_{i_1}, \ldots, i_j
\end{cases}
\]

where \( E_1 = E_2 = 1 \) and the \( E_{i_1}, \ldots, i_j \) are defined recursively by

\[
E_{i_1}, \ldots, i_j = \begin{cases}
p_{i_1}, \ldots, i_{j-1} E_{i_1}, \ldots, i_{j-1} & \text{if } i_j = 1, \\
q_{i_1}, \ldots, i_{j-1} E_{i_1}, \ldots, i_{j-1} & \text{if } i_j = 2,
\end{cases}
\]

and the \( p_{i_1}, \ldots, i_k \), \( q_{i_1}, \ldots, i_k \) are constants satisfying the following conditions like (4.8):

\[
\begin{cases}
0 \leq p_{i_1}, \ldots, i_k, q_{i_1}, \ldots, i_k \leq 1, \\
p_{i_1}, \ldots, i_k + q_{i_1}, \ldots, i_k = 1.
\end{cases}
\]

We first establish some properties of \( A_{i_1}, \ldots, i_m \), \( B_{i_1}, \ldots, i_m \), \( D_{i_1}, \ldots, i_j \) and \( E_{i_1}, \ldots, i_j \).

\[
\sum_{i_1=1}^{m} E_{i_1}, \ldots, i_j = 1.
\]
The proof of (4.13) follows from the fact that

\[ \sum_{i_1=1}^{1} E_{i_1, i_2} = E_{1, 1} + E_{1, 2} \]

\[ i_2 = 1, 2 \]

\[ = p_1 + q_1 = 1 \] and \[ \sum_{i_1}^{E_{i_1, \ldots, i_j}} = \sum_{i_1=1}^{p_{i_1}, \ldots, i_j-1} E_{i_1, \ldots, i_j-1} + q_{i_1}, \]

\[ i_k = 1, 2 \]

\[ E_{i_1, \ldots, i_j-1} = \sum_{i_1=1}^{E_{i_1, \ldots, i_j-1}} \]

Note that by (4.10),

\[ A_{i_1, \ldots, i_m} + B_{i_1, \ldots, i_m} \]

\[ = p_{i_1, \ldots, i_m} E_{i_1, \ldots, i_m} + q_{i_1, \ldots, i_m} E_{i_1, \ldots, i_m} \]

\[ = E_{i_1, \ldots, i_m} \]

Hence by (4.13), we have

\[ (4.14) \sum_{i_1=1}^{A_{i_1, \ldots, i_m} + B_{i_1, \ldots, i_m}} = 1. \]

\[ i_k = 1, 2 \]

Similarly, we can show that

\[ (4.15) \sum_{i_k=1}^{D_{i_1, \ldots, i_j}} \leq 1. \]

\[ i_k = 1, 2 \]

Furthermore, from (4.10), (4.11) and (4.12), it is trivial to see

\[ A_{i_1, \ldots, i_m} B_{i_1, \ldots, i_m} D_{i_1, \ldots, i_j} \leq 1. \]

Therefore, by (4.14),
\[
\sum_{i_1=1}^{L} \sum_{i_m=1}^{L} [C_{\ell}(A_{i_1},\ldots,i_{m-1}) + C_{\ell}(B_{i_1},\ldots,i_{m-1})]
\]
\[
\leq \sum_{i_1=1}^{L} \sum_{i_m=1}^{L} (2A_{i_1},\ldots,i_{m-1} + 2B_{i_1},\ldots,i_{m-1})
\]
\[
= \ell r.
\]

By (4.6) and (4.15), we have

\[
\sum_{j=1}^{m} \sum_{i_1=1}^{L} \sum_{i_m=1}^{L} C_{\ell-1}(D_{i_1},\ldots,i_{j-1},2m-j)
\]
\[
\leq \sum_{j=1}^{m} \sum_{i_1=1}^{L} \sum_{i_m=1}^{L} [(L-1)r + (\alpha_{\ell-1}D_{i_1},\ldots,i_{j-1},r + \beta_{\ell-1}2m-j)(\log r)m_{\ell-4}]
\]
\[
\leq \sum_{j=1}^{m} [(\alpha_{\ell-1}+L-1)r + (\beta_{\ell-1}/2)2m_j](\log r)m_{\ell-3}.
\]

Hence by (4.9) we obtain that

\[
C_{\ell}(r,2m) \leq \ell r + (\alpha_{\ell}r + \beta_{\ell}2m)(\log r)m_{\ell-3}.
\]

where \(\alpha_{\ell} = \alpha_{\ell-1} + (L-1)\) and \(\beta_{\ell} = \beta_{\ell-1}/2\).

We have proven the theorem. ■

ACKNOWLEDGMENT

I want to thank M. Schkolnick for his comments on this paper.

Let \( U_1, U_2, \ldots, U_d \) be totally ordered sets and let \( V \) be a set of \( n \) \( d \)-dimensional vectors in \( U_1 \times U_2 \times \ldots \times U_d \). A partial ordering is defined on \( V \) in a natural way. We consider the problem of finding all maximal elements of \( V \) with respect to the partial ordering. The computational complexity of the problem is defined to be the number of required comparisons of two components and is denoted by \( C_d(n) \). It is trivial that \( C_1(n) = n-1 \) and \( C_d(n) \leq O(n^2) \) for \( d \geq 2 \).
Block 20 continued:

Previous results are $C_d(n) \leq O(n \log_2 n)$ for $d = 2,3$. In this paper, we show

1. $C_d(n) \leq (n \log_2 n)^{d-2}$ for $d \geq 4$,
2. $C_d(n) \geq \lceil \log_2 n \rceil$ for $d \geq 2$.
